Therapeutic Class Overview Oral Atypical (Second-Generation) Antipsychotics

Therapeutic Class Overview/Summary:

This overview will focus on the atypical antipsychotics, which are also known as second-generation antipsychotics (SGAs). $^{1-14}$ While several atypical antipsychotics are formulated as long-acting injections, these formulations will not be covered in this review. Antipsychotic medications have been used for over fifty years to treat schizophrenia and a variety of other psychiatric disorders. 15 Schizophrenia is believed to be caused by an increase in the cerebral activity of dopamine D_2 in the mesolimbic and/or mesocortical regions of the brain. Antipsychotic medications exert their effect in part by blocking D_2 receptors. It is the blockade of these receptors in the mesolimbic pathway that is believed to contribute to desired antipsychotic effects, especially improvement of positive symptoms associated with the disorder. 16

In addition to blocking D₂ receptors in the mesolimbic pathway, FGAs also block D₂ receptors in the mesocortical, tuberoinfundibular, and nigrostriatal pathways. ¹⁶ D₂ blockade in these other pathways is thought to be responsible for the hyperprolactinemia and extrapyramidal symptoms (EPS) associated with this class. ¹⁷ FGAs may be characterized according to their affinity for the D₂ receptor. Low potency antipsychotics, such as chlorpromazine and thioridazine, are more sedating and associated with a higher incidence of anticholinergic side effects. Fluphenazine, haloperidol, pimozide, thiothixene, and trifluoperazine are high potency antipsychotics that are less sedating but associated with a higher incidence of EPS. The medium potency antipsychotics (loxapine, molindone, and perphenazine) possess a moderate risk of EPS and anticholinergic side effects. ¹⁸ With the exception of pimozide, all FGAs are indicated for use in the treatment of schizophrenia. FGAs are effective in the treatment of positive symptoms of schizophrenia, which include agitation, aggression, delusions, and hallucinations. Negative symptoms of schizophrenia which include avolition, anhedonia, alogia, affective flattening, and social withdrawal, do not respond as well to this antipsychotic class. ¹⁷ Pimozide is indicated only for the suppression of motor and phonic tics in patients with Tourette's disorder.

The term "atypical antipsychotic" was introduced in 1989 when clozapine was approved for use by the Food and Drug Administration (FDA). Originally, this term referred to an antipsychotic with a low risk of EPS. ¹⁸ As a class, SGAs or atypical antipsychotics are more selective in targeting the mesolimbic D₂ pathway. They also block or partially block serotonin (5-HT)_{2A} and 5-HT_{1A} receptors and have a greater affinity for 5-HT₂ receptors than D₂ receptors. ^{16,18} These differences in neuropharmacologic activity are associated with a lower risk of EPS and tardive dyskinesia; the risks vary with the specificity of each agent for D₂ and serotonin receptors. ^{16,18} Atypical antipsychotics have a more favorable outcome in the treatment of the negative symptoms of schizophrenia. ¹⁶ The SGAs are comprised of nine separate chemical entities, each with a unique neuropharmacologic and adverse event profile, mechanism of action, and chemical structure. The SGAs are aripiprazole, asenapine, brexpiprazole clozapine, iloperidone, lurasidone, olanzapine, paliperidone, quetiapine, risperidone and ziprasidone.

Although in some respects the SGAs are safer and better tolerated than the FGAs, they are still associated with a number of serious risks and side effects. For this reason, the FDA has required various warnings to be inserted in the manufacturers' product information for these agents. All bear a warning that alerts prescribers and patients to the risk of hyperglycemia and other metabolic changes. ¹⁻¹⁴ Ziprasidone also has a warning concerning QTc interval prolongation; however, all of the SGAs can increase the QTc interval to some degree. ¹⁻¹⁴ Aripiprazole, brexpiprazole, lurasidone and quetiapine carry a black box warning regarding suicidality and antidepressant drugs. ^{1,3,8,11,12} All SGAs carry a black box warning noting that they are associated with an increased risk of death when used in the treatment of psychosis and behavioral problems in elderly patients with dementia. Most of the deaths that prompted the addition of the warning were due to cardiac-related events (e.g., heart failure or sudden death) or infection. ²¹ Of note, this last black box warning is directed at using antipsychotics in a manner that is not FDA-approved.

Due to the potential side-effect risks associated with these medications, any off-label use deserves close attention. Data published in peer-reviewed journals and in national and international guidelines support the use of SGAs as a treatment option for certain off-label uses. In many of these scenarios, SGAs are reserved for patients who are refractory to other first-line treatment modalities, including both pharmacotherapy and psychotherapy, and used in adjunction to mainstream therapies, as part of a multimodal approach.

Over the past 20 years, antipsychotic use in children and adolescents has grown. In the United States, the frequency of prescribing an antipsychotic agent increased from 8.6 per 1000 children in 1996 to 39.4 per 1000 children in 2002. According to a survey of national trends in the outpatient use of antipsychotics in children and adolescents, only 14.2% of antipsychotic prescriptions in children were for patients diagnosed with psychotic disorders. ²² Indications commonly associated with antipsychotic prescribing in pediatric patients include psychosis, schizophrenia, bipolar disorder, aggressive and disruptive behavior, and tic disorders. Off-label indications with limited available evidence for the use of atypical antipsychotics in children and adolescents include autistic spectrum disorders, major depressive disorder, anxiety disorders, and eating disorders. At this time, risperidone and aripiprazole are FDA-approved for the management of children and adolescents with autism (aged 5 to 16 and 6 to 17 years, respectively). Moreover, the following agents are indicated for the treatment of schizophrenia in adolescents: aripiprazole, olanzapine, paliperidone, quetiapine, and risperidone. Aripiprazole, asenapine, olanzapine, quetiapine and risperidone are FDA-approved for the treatment of manic or mixed bipolar I disorder in children and adolescents. None of the other available atypical antipsychotic agents are currently indicated for use in pediatric patients. ¹⁻¹⁴

Concerns have also been raised about the risks of combination therapy with the antipsychotics, which can multiply the risks of dangerous adverse events. The practice of polypharmacy is not supported by well-designed clinical trials published in the peer-reviewed literature. However, national and international consensus guidelines consider this approach in patients with treatment-refractory illness.

Table 1. Current Medications Available in Therapeutic Class¹⁻¹⁴

Generic Name	Food and Drug Administration Approved	Dosage	Generic
(Trade name)	Indications	Form/Strength	Availability
	•		
	associated with autistic disorder in children and adolescents aged six to 17 years		

Generic Name	Food and Drug Administration Approved	Dosage	Generic

Evidence-based Medicine

- The Clinical Antipsychotic Trials of Intervention Effectiveness (CATIE) was a large, multi-center study initiated by the National Institute of Mental Health to examine the effectiveness of second generation antipsychotics (SGAs) compared to first generation antipsychotics (FGAs) in patients with chronic schizophrenia. Among the unexpected outcomes was the finding that, with the exception of clozapine, the SGAs did not separate out as robustly from the FGAs with respect to overall efficacy and times to treatment discontinuation.
 - Due to relatively high discontinuation rates across all treatment arms, potential biases regarding optimal dosing of individual drugs, and clear differences in treatment-emergent side effect profiles, the implications of CATIE are subject to interpretation which may preclude definitive guidance in developing pharmacotherapy guidelines for patients with schizophrenia as a whole.
- The role of the SGAs has been clearly established in the treatment of bipolar disorder and schizophrenia (and, in the case of aripiprazole, quetiapine extended-release and olanzapine/fluoxetine combination therapy, as adjunctive treatment of major depressive disorder).
- Meta-analyses evaluating the roles of available atypical antipsychotics in the treatment of schizophrenia suggest that all agents are significantly more effective than placebo. 46-58,68-72 The trends for respective efficacy suggest that clozapine is the most effective agent in the class, followed by olanzapine and risperidone. Aripiprazole tended to exhibit lower efficacy than the other agents. 46-55,68-72
- A meta-analysis in adult patients with bipolar disorder found risperidone to be the most effective treatment option (taking into account both efficacy and tolerability).⁶⁸ The next best treatment options, in order of decreased efficacy, were olanzapine, haloperidol, quetiapine, carbamazepine, aripiprazole, valproate, lithium, and ziprasidone. Lamotrigine, topiramate and gabapentin were found to be less effective than placebo.
- In the management of major depressive disorder, aripiprazole, quetiapine, and risperidone augmentation therapies were associated with improved outcomes.

- The efficacy and safety of brexpiprazole in the treatment of schizophrenia was demonstrated by two pivotal multicenter, randomized, double-blind, placebo controlled six week trials, VECTOR and BEACON.^{27,28} Positive and Negative Syndrome Scale (PANSS) scores were significantly improved with brexpiprazole when compared to placebo. Treatment differences were -8.72 (P<0.0001), -7.64 (P=0.0006) and -6.47 (P=0.0022) for brexpiprazole 2 mg, 4 mg, and 4 mg respectively.^{27,28}
- The efficacy of asenapine in the treatment of schizophrenia in adults has been evaluated in four, published, randomized, double-blind, placebo-controlled, and active-controlled (haloperidol, risperidone, and olanzapine) trials, ranging in duration from six weeks to one year²⁹⁻³². The efficacy and safety of asenapine in the treatment of manic or mixed bipolar I disorder were evaluated in five placebo-controlled, and active-controlled (olanzapine) studies in adult patients, with or without psychotic features.⁵⁹⁻⁶³
 - In a direct-comparison study, asenapine was less effective than olanzapine in terms of changes from baseline in PANSS and Clinical Global Impression-Severity of Illness (CGI-S) scores.³² Study discontinuation due to inadequate efficacy was noted in 14% of patients receiving olanzapine compared to 25% of patients in the asenapine group. Mean weight gain was 0.9 kg with asenapine and 4.2 kg with olanzapine.³² In another study, clinically significant weight gain was noted in 17% of patients receiving risperidone and 9% of patients in the asenapine group.²⁹
 - In a pooled analysis of patients experiencing bipolar mania, asenapine and olanzapine were comparable in terms of reduction from baseline in Young Mania Rating Scale (YMRS) scores at week-52 of therapy. 63
 - A meta-analysis of various antimanic therapy options, found that asenapine was associated with a statistically significant improvement in YMRS scores from baseline compared to placebo (mean difference, -0.30; -0.53 to -0.07), though it was less effective compared to olanzapine (0.22; 0.08 to 0.37).⁶⁸
- Iloperidone has been studied as monotherapy for the treatment of adult patients with an acute or subacute exacerbation of schizophrenia.
 - Three six-week, randomized, double-blind, placebo- and active comparator (risperidone and haloperidol)-controlled studies found iloperidone to be significantly more effective than placebo.³⁴
 - One four-week, placebo- and active- comparator (ziprasidone)-controlled study found a significant improvement in PANSS scores with iloperidone therapy compared to placebo. ³³
- Lurasidone has been investigated for the treatment of adult patients with acute and chronic symptoms of schizophrenia in two six-week, placebo-controlled studies and two 21-day studies directly comparing the safety and efficacy of lurasidone 120 mg once daily with ziprasidone 80 mg twice daily.³⁹⁻⁴²
 - Lurasidone and ziprasidone were comparable in terms of reduction in total PANSS, PANSS positive symptom, PANSS general symptom, CGI-S scores and several cognition scales. In addition, both drugs were comparable in terms of rates of discontinuation for any reason rate and discontinuation due to adverse events. Both therapies were associated with a small weight loss from baseline and neither therapy was associated with a clinically significant ECG abnormality.
 - Of note, lurasidone was more effective in improving negative symptom PANSS scores compared to ziprasidone (P=0.046).⁴¹
- Available evidence suggests that, except for clozapine, olanzapine is associated with greater weight gain compared to all other atypical antipsychotic agents. In contrast, ziprasidone is associated with a low incidence of weight gain.²¹⁴
- Data from the Food and Drug Administration Adverse Reporting System (AERS) indicates that the risk of experiencing a diabetes-related adverse event is greatest with olanzapine, followed by risperidone, and least with ziprasidone and aripiprazole, across all age groups.²⁴³
- Risperidone is associated with the greatest risk of prolactin elevation-related adverse events. 46-58,68-

- Risperidone, aripiprazole and ziprasidone are associated with a high incidence of extrapyramidal adverse events.²²² Quetiapine is associated with the least risk of extrapyramidal adverse events.²²²
- The incidence of sexual dysfunction was noted to be higher with the use of olanzapine, risperidone, and clozapine than with quetiapine, ziprasidone or aripiprazole. 226
- The Agency of Healthcare Research and Quality (AHRQ) is the lead federal agency for research on healthcare quality, costs, outcomes and patient safety. In 2011, AHRQ had issued an update to a prior 2007 review of scientific evidence on the safety and effectiveness of atypical antipsychotics for off-labeled use. ^{78, 189}
 - Indications associated with moderate/high strength of evidence for the use of atypical antipsychotics included general anxiety disorder (quetiapine), dementia (aripiprazole, olanzapine, risperidone), depression (aripiprazole, quetiapine, risperidone), augmentation of selective serotonin reuptake inhibitors for obsessive compulsive disorder [OCD] (risperidone), and post-traumatic stress disorder [PTSD] (risperidone). ⁸⁹ Refer to Appendices IIa and IIb for additional details.
- The AHRQ had conducted a systematic review of literature on the safety and efficacy of antipsychotics in children and adolescents.^{95,96} For details, refer to Appendices IIIa and IIIB.
 - Indications associated with moderate strength evidence for the use of atypical antipsychotics included disruptive behavior disorder, bipolar disorder, schizophrenia, and Tourette's syndrome.
 - No significant differences between the different atypical antipsychotics were noted in the identified head-to-head comparisons.
 - The risks of weight gain (weight gain: 4.6 kg) and dyslipidemia were highest with olanzapine.
 Weight gain with ziprasidone was not significantly different from placebo. The other atypical antipsychotics were associated with intermediate weight gain.
 - Risperidone was associated with the greatest incidence of prolactin-related adverse events (consistent with adult data).
 - Extrapyramidal adverse events were significantly more common with risperidone and aripiprazole compared to placebo.
- According to a systematic review by Safer et al, weight gain secondary to atypical antipsychotics is greater in children and adolescents than in adults.²⁵⁷

Key Points within the Medication Class

- According to Current Clinical Guidelines:
 - o Antipsychotics are a mainstay in therapy for schizophrenia. 306-308
 - Lithium, valproate and/or antipsychotics are recommended as initial therapy of bipolar disorder. ²⁹³⁻²⁹⁶
 - The American Psychiatric Association guideline recommends the use of antipsychotics for the management of psychosis or agitation in patients with dementia.²⁹⁷
 - o For the treatment of anxiety disorders, sertraline is recommended as a first-line pharmacotherapeutic agent. Second-line treatment options include serotonin norepinephrine reuptake inhibitors (SNRIs) or switching to alternative selective serotonin reuptake inhibitors (SSRIs). Augmentation therapy with antipsychotics is an option in treatment-refractory patients but the guidelines recommend that initiation of combination therapy be limited to specialists.
 - In major depressive disorder, first-line treatment options include SSRIs, SNRIs, bupropion or mirtazapine.³⁰⁰⁻³⁰² Antipsychotic augmentation therapy is an option for patients who have failed antidepressant monotherapy.
 - o In obsessive compulsive disorder, SSRIs and cognitive behavioral therapy are recommended as first-line treatment options. Patients who have failed an SSRI trial may be offered augmentation therapy with an antipsychotic or cognitive behavioral therapy. Similarly, SSRIs and SNRIs are considered to be first-line treatment options for the treatment of post-traumatic stress disorder (PTSD). 304,305
 - Atypical antipsychotics may be used as adjunctive therapy for the management of treatment-refractory PTSD.

- The European Society for the Study of Tourette Syndrome guideline recommends risperidone as a first-line agent for the treatment of tics.³¹⁹ Aripiprazole has a role in treatment-refractory patients.
- The American Academy of Child and Adolescent Psychiatry (AACAP) guideline acknowledges that atypical antipsychotics are the most commonly prescribed class of drugs for the treatment of maladaptive aggression, regardless of diagnosis; yet emphasize that pharmacotherapy should not be used as the only intervention in children with oppositional defiant disorder.³¹⁴
- Although the antipsychotics are not addressed in national and international insomnia treatment guidelines, the National Institute of Health (NIH) Consensus and State-of-the-Science Statement on Manifestations and Management of Chronic Insomnia in Adults state that due to the lack of evidence supporting the short and long term efficacy of antipsychotics, in addition to their significant risks, their use in the treatment of chronic insomnia cannot be recommended.
- o In a practice guideline on the use of atypical antipsychotics in children and adolescents, issued by the AACAP in 2011, the panel recommends that prior to initiation of antipsychotic therapy patients should undergo a thorough diagnostic assessment, evaluation for comorbid medical conditions and concomitant medications. Furthermore, a multidisciplinary plan that includes education and psychotherapy should be established. The prescriber should also have a thorough discussion of the risks and benefits of psychotropic medication.
- o Of the atypical antipsychotics, risperidone is recognized as an agent with the most substantial amount of methodologically stringent evidence for use in pediatric patients.³¹⁹
- There is almost no data to support the use of atypical antipsychotics in pre-school aged children.³¹⁹ The guideline recommends a marked amount of caution before using these agents in pre-schoolers.
- Given the risk of metabolic side-effects, pediatric patients receiving atypical antipsychotic therapy should be closely monitored for changes in weight, blood pressure, fasting plasma glucose and lipid profile.

^{*} FDA approved in children and/or adolescents

- o Paliperidone is an active metabolite of risperidone and therefore carries some similarity in chemical structure and pharmacologic effects with the parent drug.
- o The use of clozapine is limited due to a risk of agranulocytosis.
- o Aripiprazole, clozapine, olanzapine, paliperidone, quetiapine, risperidone and ziprasidone are available generically.

Appendix I: Summary of the Strength of Evidence for Off-Label Efficacy Outcomes (adopted from

2011 AHRQ systematic review)¹⁸⁹

Indication	Strength of Evidence	Findings	Conclusions
Dementia	High	The 2011 meta-analysis of PCTs, aripiprazole, olanzapine, and risperidone were superior to placebo as treatment of behavioral symptoms as measured by total scores on BEHAVE-AD, BPRS, and NPI. Effect sizes were generally considered to be "small" in magnitude.	Aripiprazole, olanzapine, and risperidone have efficacy as treatment for behavioral symptoms of dementia.
		Psychosis –risperidone was superior to placebo, as measured by thepsychosis subscales of the BEHAVE-AD, BPRS, and NPI. Results for aripiprazole did not meet conventional levels of statistical significance.	
		Agitation – Aripiprazole, olanzapine and risperidone were superior to placebo, as measured by the agitation subscales of the BEHAVE-AD, BPRS, NPI, and CMAI.	
		Three head to head trials compared atypicals; none was found superior.	
Depression			
Augmentation of SSRI/SNRI	Moderate (risperidone, aripiprazole, quetiapine) Low (olanzapine, ziprasidone)	The meta-analysis used "response" to treatment and remission as outcome. Pooling trials that reported the HAM-D as outcome, the relative risk of responding for participants taking quetiapine or risperidone was significantly higher than for	Aripiprazole, quetiapine, and risperidone have efficacy as augmentation to SSRIs/SNRIs for major depressive disorder. Olanzapine and
		placebo. Other trials reported MADRS scores; the relative risk of responding for participants taking aripiprazole was significantly higher than those taking placebo. Risperidone was included in two trials. These reported the drug	ziprasidone may also have efficacy.

Indication	Strength of Evidence	Findings	Conclusions
		superior to placebo. The relative risk of responding for participants taking aripiprazole was significantly higher than those taking placebo.	
		Olanzapine had only two trials, so pooling was not performed; the trials reported olanzapine superior to placebo.	
		In one available ziprasidone trial, the drug was superior to placebo in terms of MADRS scores. One trial compared ziprasidone at differing levels augmenting sertraline to sertraline alone. This trial found a greater improvement in CGI-S and MADRS scores augmenting with ziprasidone at 160mg than either augmentation with ziprasidone at 80mg or sertraline alone. However, there was no significant difference in HAMD-17, CGI-I or HAM-A	
Monotherapy	Moderate	Olanzapine alone was no better than placebo in improving symptoms at six or 12 weeks in three trials. Outcomes were too	Olanzapine does not have efficacy as monotherapy for major depressive disorder.
		In five PCTs, quetiapine was superior according to relative risk of both responding and remitted as measured by MADRS.	Quetiapine has efficacy as monotherapy for major depressive disorder
Obsessive Compu	Ilsive Disorder (O		
Augmentation of SSRIs	Moderate (risperidone) Low (olanzapine)	The 2006 meta-analysis pooled results of nine trials of risperidone, olanzapine, or quetiapine as augmentation therapy in patients who were resistant to treatment with SSRI. Atypical antipsychotics had a clinically important benefit,	Risperidone has efficacy in improving OCD symptoms when used as an adjunct to SSRI in treatment refractory patients.
		(measured by the Yale-Brown Obsessive-Compulsive Scale (YBOCS), when used as augmentation therapy. Relative risk of "responding" significant for augmentation with quetiapine and risperidone.	Olanzapine may have efficacy. Quetiapine is more efficacious than ziprasidone and clomipramine.

Indication	Strength of Evidence	Findings	Conclusions
		The updated 2011 meta-analysis found risperidone superior to placebo, as measured by changes in the Y-BOCS.	
		There were too few studies (two) of olanzapine augmentation to permit separate pooling of this drug. Both trials reported olanzapine superior to placebo.	
		One new head to head trial found no difference in effect between olanzapine and risperidone as SSRI augmentation. One new head to head trial found quetiapine more effective than ziprasidone as SSRI augmentation. In one new trial, quetiapine produced a significant reduction in Y-BOCS score, while clomipramine did not.	
Augmentation of citalopram	Low (quetiapine) Very low (risperidone)	One trial of risperidone reported no differences between groups in achieving a response to therapy, but patients maintained on risperidone had a significantly longer period of time to relapse compared to placebo (102 vs 85 days).	Quetiapine and risperidone may be efficacious as augmentation to citalopram in OCD patients.
		Two trials found quetiapine superior to placebo as augmentation for citalopram, according to Y-BOCS and CGI-I scores.	
Post-Traumatic Stress Disorder	Moderate (risperidone) Low (Olanzapine)	Three trials enrolled men with combat-related PTSD; these showed a benefit in sleep quality, depression, anxiety, and overall symptoms when risperidone or olanzapine was used to augment	Risperidone is efficacious in reducing combat-related PTSD symptoms when used as an adjunct to primary medication.
	Very Low (Quetiapine)	therapy with antidepressants or other psychotropic medication. Three trials of olanzapine or risperidone as monotherapy for abused women with PTSD were inconclusive regarding efficacy.	
		One trial found a three-fold decline in PTSD Scale (CAPS) scores in	

Indication	Strength of Evidence	Findings	Conclusions
		patients treated with quetiapine monotherapy compared to placebo. There were too few olanzapine studies (two) to pool; one reported olanzapine superior to placebo, while one did not. A meta-analysis of risperidone, using CAPS scores as outcome, found risperidone to be superior to placebo. In a meta-analysis by condition, atypical antipsychotics were efficacious for combat-related PTSD but not PTSD in abused	
Personality Disord	 ders	women.	
Borderline	Low (aripiprazole) Very low (quetiapine, olanzapine)	Four trials provide evidence that olanzapine is superior to placebo and may be superior to fluoxetine. The benefit of adding olanzapine to dialectical therapy in one trial was small. Two trials of olanzapine found no difference from placebo in any outcomes compared to placebo. Aripiprazole was superior to placebo in one small trial. Another trial found aripiprazole superior to placebo in improving SCL-90, HAM-D, and HAM-A scores at 8 months and less self-injury at 18 months. A trial of ziprasidone found no significant difference in CGI-BPD, depressive, anxiety, psychotic or impulsive symptoms compared to placebo at 12 weeks. One trial found quetiapine to be superior to placebo on BPRS and PANSS scales. Due to heterogeneity of outcomes, a meta-analysis could not be performed.	Olanzapine had mixed results in seven trials, aripiprazole was found efficacious in two trials, quetiapine was found efficacious in one trial, and ziprasidone was found not efficacious in one trial.

		statistical difference from placebo	
		in BMI increase at three months.	

Indication	Strength of Evidence	Findings	Conclusions
Insomnia	Very Low	In one small trial (N=13) of quetiapine, sleep outcomes were not statistically different from placebo.	Quetiapine may be inefficacious in treating insomnia.
Substance Abuse			
Alcohol	Moderate (aripiprazole) Low (quetiapine)	Two trials of aripiprazole and one of quetiapine reported percentage of patients completely abstinent during follow-up. In a pooled analysis, the effect vs placebo was insignificant.	Aripiprazole is inefficacious in treating alcohol abuse/ dependence. Quetiapine may also be inefficacious.
Cocaine	Low	Two trials of olanzapine and one of risperidone reported there was no difference in efficacy vs placebo as measured by the Addiction Severity Index (ASI).	Olanzapine is inefficacious in treating cocaine abuse /dependence. Risperidone may also be inefficacious.
Meth- amphetamine	Low	One trial found aripiprazole inefficacious in reducing use of intravenous amphetamine, as measured by urinalysis. Another trial found aripiprazole inefficacious in reducing craving for methamphetamine.	Aripiprazole is inefficacious in treating methamphetamine abuse/ dependence.
Methadone	Low	One trial of methadone-treated patients found no difference between risperidone and placebo in reduction of cocaine or heroin use.	Risperidone is an inefficacious adjunct to methadone maintenance

Appendix II: Summary of Adverse Events of Atypical Antipsychotics for Off-Label Use (adopted from 2011 AHRQ systematic review)¹⁸⁹

TOTAL ZOTT AFRICA Systematic review)						
Adverse Event	Head-to-Head Studies	Active Comparator Studies	Placebo-Controlled Studies			
Weight Gain	- Citation	- Citamos	0.000			
Elderly	In one large trial (CATIE-AD) patients who were treated with olanzapine, quetiapine, or risperidone averaged a monthly gain of 1.0, 0.7, and 0.4 lbs respectively,	More common in patients taking olanzapine than risperidone or conventional antipsychotics, particularly if their BMI was less than 25 at baseline, according to	According to the meta- analysis, more common in patients taking olanzapine and risperidone than placebo.			

Adverse Event	Head-to-Head Studies	Active Comparator Studies	Placebo-Controlled Studies			
	compared to a monthly weight loss of 0.9 lbs for placebo patients.	a large cohort study.				
Adults	More common in olanzapine patients than ziprasidone patients in one trial.	More common among patients taking olanzapine than patients taking conventional antipsychotics in three trials. More common in patients taking aripiprazole than patients taking conventional antipsychotics in one trial. More common among patients taking olanzapine than patients taking mood stabilizers in two trials.	According to the meta- analysis, more common in patients taking aripiprazole, olanzapine, quetiapine, and risperidone than placebo.			
Children/Adolescents	No head to head studies	No difference between clonidine and risperidone in one trial.	More common in patients taking risperidone in two PCTs. No difference in one small PCT of ziprasidone.			
Mortality-in the elderly Endocrine	No difference between olanzapine and risperidone according to a meta-analysis of six trials of olanzapine published in 2006.	Six large cohort studies compared mortality in elderly patients taking atypical and conventional antipsychotics. Four of these studies found a significantly higher rate of death with conventional antipsychotics, while two found no statistical difference in mortality between the drug classes.	The difference in risk for death was small but statistically significant for atypicals, according to a 2006 meta-analysis which remains the best available estimate. Sensitivity analyses found no difference between drugs in the class. Patients taking atypicals had higher odds of mortality than those taking no antipsychotics in the two cohort studies that made that comparison. There are no trials or large observational studies of ziprasidone in this population.			
Elderly	No evidence reported	No evidence reported	No difference in			
			endocrine events in			

Adverse Event	Head-to-Head Studies	Active Comparator Studies	Placebo-Controlled Studies
	Otudios	Otudies	risperidone patients in one PCT. Regarding diabetes, risk was elevated but not statistically significant in one industry-sponsored cohort study of olanzapine patients.
Adults	Diabetes more common in patients taking olanzapine than patients taking risperidone in one trial.	No evidence reported	Endocrine events more common in patients taking quetiapine, risperidone, and ziprasidone in one PCT each. More common in olanzapine in two pooled PCTs.
			Diabetes more common in patients taking quetiapine in six pooled PCTs; however, the pooled odds ratio was elevated at 1.47 but not statistically significant. More common in olanzapine patients in one PCT; the odds ratio of 5.14 was not statistically significant, with very wide confidence intervals (0.6 to 244). Lower odds of diabetes in risperidone patients in one large observational study.
Cerebrovascular Accident (CVA)	No evidence reported	Hospitalization for CVA was increased in the first week after initiation of typical antipsychotics, but not for initiation of atypicals in a large cohort study.	More common in risperidone patients than placebo according to four PCTs pooled by the manufacturer. In a meta-analysis of PCTs, risperidone was the only drug associated with an increase. More common in olanzapine than placebo according to five PCTs pooled by the manufacturer.

Therapeutic Class Review Atypical (Second-Generation) Antipsychotics

Overview/Summary

This review will focus on the atypical antipsychotics, which are also known as second-generation antipsychotics (SGAs). $^{1-14}$ While several atypical antipsychotics are formulated as long-acting injections, these formulations will not be covered in this review. Antipsychotic medications have been used for over fifty years to treat schizophrenia and a variety of other psychiatric disorders. 15 Schizophrenia is believed to be caused by an increase in the cerebral activity of dopamine D_2 in the mesolimbic and/or mesocortical regions of the brain. Antipsychotic medications exert their effect in part by blocking D_2 receptors. It is the blockade of these receptors in the mesolimbic pathway that is believed to contribute to desired antipsychotic effects, especially improvement of positive symptoms associated with the disorder. 16

In addition to blocking D_2 receptors in the mesolimbic pathway, FGAs also block D_2 receptors in the mesocortical, tuberoinfundibular, and nigrostriatal pathways. 16 D_2 blockade in these other pathways is thought to be responsible for the hyperprolactinemia and extrapyramidal symptoms (EPS) associated with this class. 17 FGAs may be characterized according to their affinity for the D_2 receptor. Low potency antipsychotics, such as chlorpromazine and thioridazine, are more sedating and associated with a higher incidence of anticholinergic side effects. Fluphenazine, haloperidol, pimozide, thiothixene, and trifluoperazine are high potency antipsychotics that are less sedating but associated with a higher incidence of EPS. The medium potency antipsychotics (loxapine, molindone, and perphenazine) possess a moderate risk of EPS and anticholinergic side effects. 18 With the exception of pimozide, all FGAs are indicated for use in the treatment of schizophrenia. FGAs are effective in the treatment of positive symptoms of schizophrenia, which include agitation, aggression, delusions, and hallucinations. Negative symptoms of schizophrenia which include avolition, anhedonia, alogia, affective flattening, and social withdrawal, do not respond as well to this antipsychotic class. 17 Pimozide is indicated only for the suppression of motor and phonic tics in patients with Tourette's disorder.

The term "atypical antipsychotic" was introduced in 1989 when clozapine was approved for use by the Food and Drug Administration (FDA). Originally, this term referred to an antipsychotic with a low risk of EPS. ¹⁸ As a class, SGAs or atypical antipsychotics are more selective in targeting the mesolimbic D₂ pathway. They also block or partially block serotonin (5-HT)_{2A} and 5-HT_{1A} receptors and have a greater affinity for 5-HT₂ receptors than D₂ receptors. ^{16,18} These differences in neuropharmacologic activity are associated with a lower risk of EPS and tardive dyskinesia; the risks vary with the specificity of each agent for D₂ and serotonin receptors. ^{16,18} Atypical antipsychotics have a more favorable outcome in the treatment of the negative symptoms of schizophrenia. ¹⁶ The SGAs are comprised of nine separate chemical entities, each with a unique neuropharmacologic and adverse event profile, mechanism of action, and chemical structure. The SGAs are aripiprazole, asenapine, brexpiprazole clozapine, iloperidone, lurasidone, olanzapine, paliperidone, quetiapine, risperidone and ziprasidone.

The neuropharmacology of aripiprazole differs from other SGAs, as it is a partial D_2 and 5-HT $_{1A}$ agonist and a 5-HT $_{2A}$ and 5-HT $_{2C}$ antagonist. It is referred to as a D_2 -serotonin system stabilizer since the partial agonist activity allows for blockade of an overstimulated receptor and stimulation of a receptor when activity is needed. EPS rates comparable to placebo may be attributable to the partial-agonist activity of this agent. Aripiprazole is FDA-approved for use in schizophrenia in adults and adolescents, acute manic and mixed episodes associated with bipolar disorder in adults and adolescents, agitation associated with schizophrenia or bipolar disorder in adults, irritability associated with autistic disorder in children and adolescents and major depressive disorder in adults. 1

Asenapine is the first antipsychotic agent that is solely available in the United States as a sublingual tablet formulation. It is approved for the treatment of schizophrenia in adults and acute treatment of manic or mixed episodes associated with bipolar I disorder in adults, either as monotherapy or adjunctive therapy.² It is also approved for acute use in children 10 to 17 years of age for the treatment of manic or

mixed episodes of bipolar I disorder. It has a distinctive receptor binding profile in that it displays high affinity binding and antagonistic activity at a wide range of dopamine, serotonin, norepinephrine, and histamine receptors $(H_1)^2$

Brexpiprazole is FDA-approved for the adult treatment of schizophrenia and as an adjunctive treatment in major depressive disorder. It is hypothesized that the efficacy of brexpiprazole may be mediated through a combination of partial agonist activity at serotonin 5-HT_{1A} and dopamine D_2 receptors, and antagonist activity at serotonin 5-HT_{2A} receptors.³

Clozapine has a high affinity for 5-HT receptors and a lower, transient affinity for D_2 receptors. Its use is limited by its risk of agranulocytosis. In addition to a boxed warning for agranulocytosis, clozapine also carries a boxed warning for cardiac toxicity, seizures, orthostatic hypotension, and respiratory and cardiac arrest. Clozapine is effective in patients who do not respond to conventional or other atypical antipsychotics. It is approved for use in severely ill patients with schizophrenia or those with schizophrenia or schizoaffective disorder at risk for suicidal behavior. Clozapine is now also formulated as an oral solution.

lloperidone is indicated for the acute treatment of adults with schizophrenia. Iloperidone is thought to exert its pharmacological effects via antagonism of the D_2 and 5-HT_2 receptors, with high affinity for 5-HT_{2A} , D_2 and D_3 receptors and low affinity for 5-HT_{1A} , D_1 and D_3 receptors. Iloperidone treatment may be associated with QTc prolongation. Iloperidone must be titrated to an effective dose which may delay symptom control during the first two weeks of therapy; therefore, this must be considered when choosing an agent for the acute treatment of schizophrenia.

Lurasidone is indicated for the treatment of adults with schizophrenia and for the treatment of depressive episodes associated with bipolar disorder. It is a high affinity antagonist at D_2 receptors and $5\text{-HT}_{2A}/5\text{-HT}_7$ receptors, a moderate affinity antagonist at alpha_{2C} adrenergic receptors, a partial agonist at 5-HT_{1A} receptors and is an antagonist at alpha_{2A} adrenergic receptors. Lurasidone has little to no affinity for histamine₁ and muscarinic receptors. To insure optimal absorption and distribution, the drug should be taken with food (at least 350 calories). Lurasidone is primarily metabolized in the liver via the CYP3A4 enzyme. Consequently, coadministration with strong CYP3A4 inducers or inhibitors is contraindicated. 8,19

Olanzapine is approved for use in the treatment of adults and adolescents with schizophrenia, manic or mixed episodes associated with bipolar I disorder in adults and adolescents, and agitation associated with schizophrenia or bipolar disorder. Olanzapine has a dose-dependent risk of EPS and hyperprolactinemia related to higher D_2 receptor occupancy.

Quetiapine is approved for use in the treatment of adults and adolescents with schizophrenia, adults and adolescents with acute manic episodes, and adults with depressive episodes associated with bipolar disorders. Likely due to its low and transient occupancy of D₂ receptors, quetiapine is associated with a low incidence of EPS and has not been shown to significantly elevate prolactin levels.

Risperidone is approved by the FDA for the treatment of schizophrenia and acute manic or mixed episodes associated with bipolar disorder in adults and adolescents. ¹³ Risperidone is also indicated for the management of irritability associated with autism. Compared to other SGAs, risperidone results in a higher incidence of prolactin level elevation and EPS, particularly at doses above 6 mg per day. Paliperidone, the active metabolite of risperidone, is also approved by the FDA for the treatment of schizophrenia in adults and adolescents. Moreover, paliperidone is indicated for the treatment of schizoaffective disorder as an adjunct to mood stabilizers and/or antidepressants. This medication is available in an extended-release formulation and has been shown to have an incidence of EPS similar to placebo at daily doses up to 6 mg. ¹⁰²⁰

Ziprasidone is indicated for the treatment of schizophrenia and manic or mixed episodes associated with bipolar disorder (with or without psychotic features). ¹⁴ Ziprasidone differs from other medications in its

class as it has a high affinity for D₂ receptors but a greater affinity for 5-HT₂ receptors. The higher affinity for the 5-HT₂ receptors may reduce the incidence of EPS, but this risk is dose dependent. It also possesses potent serotonin and norepinephrine reuptake blocking effects.

Although in some respects the SGAs are safer and better tolerated than the FGAs, they are still associated with a number of serious risks and side effects. For this reason, the FDA has required various warnings to be inserted in the manufacturers' product information for these agents. All bear a warning that alerts prescribers and patients to the risk of hyperglycemia and other metabolic changes. ¹⁻¹⁴ Ziprasidone also has a warning concerning QTc interval prolongation; however, all of the SGAs can increase the QTc interval to some degree. ¹⁻¹⁴ Aripiprazole, brexpiprazole, lurasidone and quetiapine carry a black box warning regarding suicidality and antidepressant drugs. ^{1,3,8,11,12} All SGAs carry a black box warning noting that they are associated with an increased risk of death when used in the treatment of psychosis and behavioral problems in elderly patients with dementia. Most of the deaths that prompted the addition of the warning were due to cardiac-related events (e.g., heart failure or sudden death) or infection. ²¹ Of note, this last black box warning is directed at using antipsychotics in a manner that is not FDA-approved.

Due to the potential side-effect risks associated with these medications, any off-label use deserves close attention. Data published in peer-reviewed journals and in national and international guidelines support the use of SGAs as a treatment option for certain off-label uses. In many of these scenarios, SGAs are reserved for patients who are refractory to other first-line treatment modalities, including both pharmacotherapy and psychotherapy, and used in adjunction to mainstream therapies, as part of a multimodal approach.

Over the past 20 years, antipsychotic use in children and adolescents has grown. In the United States, the frequency of prescribing an antipsychotic agent increased from 8.6 per 1000 children in 1996 to 39.4 per 1000 children in 2002. According to a survey of national trends in the outpatient use of antipsychotics in children and adolescents, only 14.2% of antipsychotic prescriptions in children were for patients diagnosed with psychotic disorders. ²² Indications commonly associated with antipsychotic prescribing in pediatric patients include psychosis, schizophrenia, bipolar disorder, aggressive and disruptive behavior, and tic disorders. Off-label indications with limited available evidence for the use of atypical antipsychotics in children and adolescents include autistic spectrum disorders, major depressive disorder, anxiety disorders, and eating disorders. At this time, risperidone and aripiprazole are FDA-approved for the management of children and adolescents with autism (aged 5 to 16 and 6 to 17 years, respectively). Moreover, the following agents are indicated for the treatment of schizophrenia in adolescents: aripiprazole, olanzapine, paliperidone, quetiapine, and risperidone. Aripiprazole, asenapine, olanzapine, quetiapine and risperidone are FDA-approved for the treatment of manic or mixed bipolar I disorder in children and adolescents. None of the other available atypical antipsychotic agents are currently indicated for use in pediatric patients. ¹⁻¹⁴

Concerns have also been raised about the risks of combination therapy with the antipsychotics, which can multiply the risks of dangerous adverse events. The practice of polypharmacy is not supported by well-designed clinical trials published in the peer-reviewed literature. However, national and international consensus guidelines consider this approach in patients with treatment-refractory illness.

Medications

The second-generation antipsychotics that are included in this review are listed in Table 1. This review encompasses all oral dosage forms and immediate release injections.

Table 1. Medications Included Within Class Review

Generic Name (Trade name)	Medication Class	Generic Availability
Aripiprazole (Abilify®*, Abilify Discmelt®)	Atypical antipsychotic	а
Asenapine (Saphris®)	Atypical antipsychotic	-
Brexpiprazole (Rexulti®)	Atypical antipsychotic	-
Clozapine (Fazaclo ODT®*, Clozaril®*, Versacloz®)	Atypical antipsychotic	а
lloperidone (Fanapt [®])	Atypical antipsychotic	-
Lurasidone (Latuda [®])	Atypical antipsychotic	-
Olanzapine (Zyprexa [®] *, Zyprexa IM [®] *, Zyprexa Zydis [®] *)	Atypical antipsychotic	а
Paliperidone (Invega®*)	Atypical antipsychotic	а
Quetiapine (Seroquel®*, Seroquel XR®)	Atypical antipsychotic	а
Risperidone (Risperdal [®] *, Risperdal M-Tab [®] *)	Atypical antipsychotic	а
Ziprasidone (Geodon®*)	Atypical antipsychotic	а

IM=intramuscular, ODT=orally disintegrating tablet, XR=extended release *Generic is available in at least one dosage form or strength.

^{*}Oral dosage form(s).

Oral extended-release dosage form.

A number of the atypical antipsychotics have been studied and used off-label for a variety of treatments.

[†]Intramuscular dosage form.

[#] Approved for acute treatment only.

[§] In choosing among treatments, prescribers should consider the ability of Fanapt® to prolong the QT interval and the use of other drugs first. Prescribers should also consider the need to titrate Fanapt® slowly to avoid orthostatic hypotension, which may lead to delayed effectiveness compared to some other drugs titration.

Tonly approved when used in combination with fluoxetine

[#] Indicated for the treatment depression in patients who do not respond to 2 separate trials of different antidepressants of adequate dose and duration in the current episode.

^{**} Medical treatment of both pediatric schizophrenia and bipolar I disorder should be part of a total treatment program that includes psychological, educational, and social interventions. The increased potential for weight gain and hyperlipidemia, in adolescents compared to adults, may lead clinicians to consider prescribing other drugs first in adolescents.

Pharmacokinetics

Table 3. Pharmacokinetics 1-14

Drugs(s)	Bioavailability (%)	Protein Binding (%)	Renal Excretion (%)	Active Metabolites	Serum Half- Life (hours)
Aripiprazole	87*; 100†	>99	25	Dehydroaripiprazole	75 to 146

Ziprasidone	60*; 100†	>99	Not reported	Not reported	2 to 5

^{*}Oral dosage form.

Clinical Trials

Numerous clinical studies evaluating the efficacy of antipsychotic medications have been conducted for both Food and Drug Administration (FDA)-approved and non-approved indications. ²³⁻²⁹⁰ The available published literature describing the safety and efficacy of atypical antipsychotic agents for both off-label and FDA-approved indications in adults, children and adolescents are included in Table 4 to Table 9.

The efficacy and safety of brexpiprazole in the treatment of schizophrenia was demonstrated by two pivotal multicenter, randomized, double-blind, placebo controlled six week trials, VECTOR and BEACON. PECTOR, the average effect of brexpiprazole 2 mg and 4 mg on the primary efficacy endpoint (Positive and Negative Syndrome Scale [PANSS] scores) measure was statistically significant compared to placebo with greater mean improvements in PANSS total score at week six (P<0.0001). The treatment differences were –8.72 (P<0.0001) and –7.64 (P=0.0006) for brexpiprazole 2 mg and 4 mg, respectively. BEACON also showed a significantly improved PANSS score with brexpiprazole 4 mg compared with placebo. The treatment difference was –6.47 (P=0.0022). Both studies showed

[†]Intramuscular dosage form.

[‡]Active metabolite.

statistically significant improvements in Clinical Global Impressions-Severity (CGI-S) scores (P value not reported for VECTOR, P=0.0015 for BEACON). 27,28

The efficacy and safety of brexpiprazole in the adjunctive treatment of major depressive disorder was demonstrated by two pivotal multicenter, randomized, double-blind, placebo controlled six week trials. Pooled analysis of the two trials showed greater improvement with adjunctive brexpiprazole compared to placebo in Montgomery-Asberg Depression Rating Scale (MADRS) total score (least squares mean difference to placebo was brexpiprazole 1 mg, -2.02; P=0.0018, brexpiprazole 2 mg, -2.35; P=0.0007 and brexpiprazole 3 mg, -2.54; P=0.0001).

The efficacy of asenapine in the treatment of schizophrenia in adults has been evaluated in four, published, randomized, double-blind, placebo-controlled, and active-controlled (haloperidol, risperidone, and olanzapine) trials, ranging in duration from six weeks to one year. 29-32 Asenapine was associated with statistically significant improvement in the PANSS scores from baseline compared to placebo, starting from week two of therapy. Clinical Global Impression-Improvement (CGI-I) and Clinical Global Impression-Severity of Illness (CGI-S) scores were also significantly improved with asenapine therapy. compared to placebo. Moreover, an extension study demonstrated a reduced risk of relapse associated with continuation of asenapine therapy. 31 However, a direct-comparison study suggests that asenapine is less effective than olanzapine in terms of changes from baseline in PANSS and CGI-S scores.³² Furthermore, study discontinuation due to inadequate efficacy was noted in only 14% of patients receiving olanzapine compared to 25% of patients in the asenapine group. Mean weight gain was 0.9 kg with asenapine and 4.2 kg with olanzapine. 32 In another study, while 17% of patients receiving risperidone experienced a weight gain of at least 7% from baseline, 9% of patients in the asenapine were noted to exhibit clinically significant weight gain.²⁹ The efficacy and safety of asenapine in the treatment of manic or mixed bipolar I disorder were evaluated in five placebo-controlled, and active-controlled (olanzapine) studies in adult patients, with or without psychotic features. 59-63 Asenapine 5 to 10 mg twice daily was statistically more effective than placebo on the Young Mania Rating Scale (YMRS) and the Clinical Global Impression-Bipolar Scale (CGI-BS) in all studies. In a pooled analysis of patients experiencing bipolar mania, asenapine and olanzapine were comparable in terms of reduction from baseline in YMRS scores 5 weeks2 of therapy. 63 Likewise, another pooled analysis of patients experiencing bipolar depression episode found that olanzapine and asenapine were associated with comparable improvement in baseline Montgomery-Asberg Depression Rating Scale (MADRS) scores after 21 days of therapy. 61 A metaanalysis of various antimanic therapy options, found that asenapine was associated with a statistically significant improvement in YMRS scores from baseline compared to placebo (mean difference, -0.30; -0.53 to -0.07), though it was less effective compared to olanzapine (0.22; 0.08 to 0.37). 68 In addition, another meta-analysis calculated that six patients would be treated with asenapine for one to achieve a positive response, compared to placebo. 46 Most commonly reported adverse events reported with asenapine included sedation, dizziness, somnolence and weight gain. ⁷⁵ Of note, it was calculated that for every nine patients treated with olanzapine over asenapine, one would experience a clinically significant weight gain.61

lloperidone was studied as monotherapy for the treatment of adult patients with an acute or subacute exacerbation of schizophrenia. Three, six-week, randomized, double-blind, placebo- and active comparator (risperidone and haloperidol)-controlled studies found iloperidone to be significantly more effective than placebo. Another four week, placebo- and active- comparator (ziprasidone)-controlled study found a significant improvement in PANSS scores with iloperidone therapy compared to placebo. Two meta-analyses of these four studies corroborated earlier data, finding iloperidone more effective than placebo in terms of improvement from baseline in various subscales of the PANSS scale and BPRS scores. The long-term efficacy and safety of iloperidone in the treatment of schizophrenia was evaluated in a meta-analysis that pooled the follow-up data (up to 52 weeks) from three prospective randomized clinical trials. The meta-analysis found the long-term efficacy of lloperidone, assessed via the time to relapse endpoint, to be comparable to haloperidol (P=0.85), with a more favorable long-term safety profile. Moreover, another meta-analysis designed to evaluate the short-term safety of iloperidone found the following dose-related adverse effects: dry mouth, dizziness, somnolence and dyspepsia.

EPS adverse events were noted in association with iloperidone but were more common with haloperidol and risperidone therapies. Iloperidone was also associated with QTc prolongation and weight gain (1.5 kg to 2.1 kg).³⁸

Lurasidone has been investigated for the treatment of adult patients with acute and chronic symptoms of schizophrenia in two six-week, placebo-controlled studies and two 21-day studies directly comparing the safety and efficacy of lurasidone 120 mg once daily with ziprasidone 80 mg twice daily. 39-42 In placebo controlled studies, lurasidone, dosed 40 mg, 80 mg, or 120 mg once daily was associated with significant improvements from baseline in PANSS and the Brief Psychiatric Rating Scale (BPRSd) scores, compared to placebo. 39,42 The two direct-comparison studies demonstrated comparable improvements in the lurasidone and ziprasidone groups in terms of the reduction in total PANSS, PANSS positive symptom, PANSS general symptom, CGI-S scores and several cognition scales. 40,41 Likewise, the two groups were comparable in terms of rates of discontinuation for any reason rate and discontinuation due to adverse events. 40,41 Of note, lurasidone was more effective in improving negative symptoms PANSS scores compared to ziprasidone (P=0.046).⁴¹ Both therapies were associated with a small weight loss from baseline and neither therapy was associated with a clinically significant ECG abnormality. EPS adverse events were noted in 3.3% of patients in the ziprasidone group and in 3.3% of patients receiving lurasidone. 41 Two studies conducted evaluated the effectiveness of lurasidone for bipolar depression. The least squares mean change from baseline to week six in MADRS and Clinical Global Impression-Bipolar Illness (CGI-BP depression score after six weeks (P<0.001 for both trials). Median time to response was also significantly shorter for the lurasidone group compared with placebo (P<0.001 for both trials). 285,286

Evaluation of the atypical antipsychotics as a whole for the treatment of schizophrenia was done via a systemic review and a meta-analysis. Asmal et al directly compared quetiapine to other atypical in a systemic review, while Leucht et al reviewed oral atypical antipsychotics compared to placebo or another atypical antipsychotic in a meta-analysis. Both found generally the atypical antipsychotics were efficacious with minor differences between studies on what which is more effective. ^{282,283} It is important to note that both trials noted distinct differences in side effects. Quetiapine may produce fewer parkinsonian effects than paliperidone, aripiprazole, ziprasidone, risperidone and olanzapine. Quetiapine appears to have a similar weight gain profile to risperidone, as well as clozapine and aripiprazole (although data are very limited for the latter two comparators). Quetiapine may produce greater weight gain than ziprasidone and less weight gain than olanzapine and paliperidone. ²⁸²

A systematic review evaluating the use of atypical antipsychotics in patients aged 13 to 17 years for the short term management of schizophrenia was done by Kumar et al. No convincing evidence suggests that atypical antipsychotic medications are "superior" to typical medications for the treatment of adolescents with psychosis. However, atypical antipsychotic medications may be more acceptable to young people because fewer symptomatic adverse effects are seen in the short term. Little evidence is available to support the "superiority" of one atypical antipsychotic medication over another, but side effect profiles are different for different medications.²⁸⁴

The Clinical Antipsychotic Trials of Intervention Effectiveness (CATIE) was a large, multi-center study initiated by the National Institute of Mental Health to examine the effectiveness of SGAs compared to first generation antipsychotics (FGAs) in patients with chronic schizophrenia. It was intended to include patients treated in typical clinical settings and to reflect typical clinical practice in which individuals with schizophrenia may require multiple medication trials before finding one that is adequately both efficacious and tolerable. The study design allowed for patients who discontinued one study antipsychotic drug to enter subsequent phases of the study to receive additional antipsychotic medications. ⁴³⁻⁴⁵ Among the unexpected outcomes was the finding that, with the exception of clozapine, the SGAs did not separate out as robustly from the FGAs with respect to overall efficacy and times to treatment discontinuation. However, because of relatively high discontinuation rates across all treatment arms, potential biases regarding optimal dosing of individual drugs, and clear differences in treatment-emergent side effect profiles, the implications of CATIE are subject to interpretation which may preclude definitive guidance in developing pharmacotherapy guidelines for patients with schizophrenia as a whole.

Risperidone oral solution or oral aripiprazole compared to placebo was evaluated for the use in irritability associated with autism. Kent et al evaluated irritability and CGI-S scores, and found they were significantly improved after six weeks with only high-dose risperidone (1.25 to 1.75 mg/day; P<0.001 and P=0.004, respectively) compared to placebo and not low-dose risperidone (0.125 to 0.175 mg/day; P=0.164 and P=0.817, respectively) compared to placebo. ²⁸⁷ Findling et al evaluated relapse rates for patients who had irritability associated with autism. Relapse rates at week 16 were 35% for aripiprazole and 52% for placebo, for a hazard ratio (aripiprazole/placebo) of 0.57 (95% confidence interval [CI], 0.28 to 1.12). The mean time until 25% of patients treated with aripiprazole relapsed was 56 days (95% CI, 31 to undefined), and, for placebo, it was 29 days (95% CI, 25 to 45), representing a difference that was not statistically significant (P=0.097). A post hoc analysis demonstrated a number needed to treat of six (95% CI, 2.58 to not approached) to prevent one additional relapse.

The Agency of Healthcare Research and Quality (AHRQ) is the lead federal agency for research on healthcare quality, costs, outcomes and patient safety. Under the Medicare Prescription Drug, Improvement, and Modernization Act of 2003, the AHRQ is required to conduct and support research into the clinical effectiveness, comparative effectiveness, and appropriateness of pharmaceuticals, medical devices and healthcare services for the recipients of Medicare, Medicaid, and the State Children's Health Insurance Program. 95,198

In 2011, AHRQ had issued an update to a prior 2007 review of scientific evidence on the safety and effectiveness of atypical antipsychotics for off-labeled use. Specifically, asenapine, aripiprazole, iloperidone, olanzapine, paliperidone, quetiapine, risperidone, and ziprasidone were evaluated for off-labeled uses, such as anxiety disorders, attention deficit hyperactivity disorder (ADHD), dementia and severe geriatric agitation, depression, eating disorder, insomnia, obsessive-compulsive disorder, posttraumatic stress disorder, personality disorders, substance abuse, Tourette's syndrome and autism. Efficacy analyses included controlled trials of at least six weeks in duration. Results from efficacy studies judged clinically similar were pooled in a meta-analysis. For trials judged not clinically similar, a narrative synthesis was performed. Adverse events analysis included trials of any duration, case series or cohort studies with a comparison group of >1,000 patients. Following analysis and synthesis of data, the draft report was reviewed by a technical expert panel consisting of scientists and clinicians with expertise in psychiatric conditions. Of note, no pertinent studies with asenapine, iloperidone or paliperidone met the inclusion criteria and were thus not included in the final evaluation of results.

The overall strength of evidence was assessed using a grading method developed by the Grade Working Group. The classification criteria are as follows 198:

- High= High confidence that the evidence reflects the true effect. Further research is very unlikely to change the confidence on the estimate of effect.
- Moderate= Moderate confidence that the evidence reflects the true effect. Further research may change the confidence in the estimate of effect and may change the estimate.
- Low= Low confidence that the evidence reflects the true effect. Further research is likely to change the confidence in the estimate of effect and is likely to change the estimate.

The AHRQ evidence grading system took into account the following factors: risk of bias, consistency, directness, precision, dose-response, potential confounders that would decrease the observed effect, strength of association, and publication bias. In summary, indications associated with moderate/high strength of evidence for the use of atypical antipsychotics included general anxiety disorder (quetiapine), dementia (aripiprazole, olanzapine, risperidone), depression (aripiprazole, quetiapine, risperidone), augmentation of SSRIs for obsessive compulsive disorder [OCD] (risperidone), and post-traumatic stress disorder [PTSD] (risperidone). In addition, the AHRQ had conducted a systematic review of literature on the safety and efficacy of antipsychotics in children and adolescents. Ps. The review included studies of atypical antipsychotics (aripiprazole, clozapine, olanzapine, quetiapine, risperidone, paliperidone, and ziprasidone), conducted in patients 24 years of age or younger, used for the following FDA-approved and off-label indications: pervasive developmental disorder, ADHD/disruptive behavior disorders, bipolar

disorder, schizophrenia, psychosis, Tourette's syndrome, OCD, PTSD, anorexia nervosa, and miscellaneous behavioral issues. In summary, indications associated with moderate strength evidence for the use of atypical antipsychotics included disruptive behavior disorder, bipolar disorder, schizophrenia, and Tourette's syndrome. No significant differences between the different atypical antipsychotics were noted in the identified head-to-head comparisons. The risks of weight gain (weight gain: 4.6 kg) and dyslipidemia were highest with olanzapine. Weight gain with ziprasidone was not significantly different from placebo. The other atypical antipsychotics were associated with intermediate weight gain. Risperidone was associated with the greatest incidence of prolactin-related adverse events (consistent with adult data). EPS adverse events were significantly more common with risperidone and aripiprazole compared to placebo. For details of these findings, refer to Table 6 and Appendices IIa and IIB.

Table 4. Efficacy Clinical Trials Using the Antipsychotics

	Study Design	Sample Size		
Study and Drug Regimen	and	and Study	End Points	Results
	Demographics	Duration		
Acute Psychotic Symptoms				
Hatta et al ²³	MC, OL	N=87	Primary: PANSS-EC, CGI-C,	Primary: There were no significant main effects on treatment (P=0.09), and no

Time to discontinuation for any reason was longer with olanzapine (median, 6.3 months) and risperidone (7.0 months) than with the quetiapine (4.0 months) and ziprasidone (2.8 months) groups (P=0.004 for overall group difference). Secondary: There were no differences among treatment groups regarding discontinuation due to lack of efficacy or intolerable side effects. In those patients who discontinued previous therapy due to inefficacy, olanzapine was more effective than quetiapine and ziprasidone, and risperidone was more effective than quetiapine (P=0.004 among groups). There were no significant differences between groups in those who discontinued previous treatment due to intolerability (P value not reported). There were significantly greater improvements in PANSS scores with olanzapine than with quetiapine (estimated MD, -6.8; P=0.005) and ziprasidone (estimated MD, -5.9; P=0.005), but not with risperidone. There were no differences in changes in CGI scores between treatment groups (P values not reported). Hospitalizations due to schizophrenia exacerbation were lower with olanzapine (0.28) than with risperidone (0.40), ziprasidone (0.48), and quetiapine (0.70). Common adverse events included sexual dysfunction (highest with risperidone, 29%), insomnia (ziprasidone, 31%), orthostatic faintness (quetiapine, 13%), weight gain (olanzapine, 1.3 lb/month), increases in total cholesterol (olanzapine, mean, -17.5 mg/dL), prolactin (risperidone, mean, 24.0 ng/mL), and triglycerides (mean, 94.1 mg/dL).

aripiprazole, clozapine, olanzapine, perphenazine, quetiapine, risperidone, or ziprasidone or fluphenazine decanoate or combination of any two of these treatments	schizophrenia, a condition appropriate for treatment with an oral medication, and have the decision-making capacity to make choices and provide informed consent who had discontinued treatment in CATIE Phase 2		Secondary: Reason for treatment discontinuation, PANSS scores, CGI ratings, safety and tolerability outcomes	the proportion of possible treatment time that patients stayed on treatment (67%-80%). Secondary: A greater number of patients discontinued therapy with aripiprazole (18%), olanzapine (15%), and combination antipsychotic treatment (13%) for lack of efficacy compared to clozapine (5%), risperidone (3%), quetiapine (6%), and ziprasidone (8%). In terms of efficacy measures, there were no differences among mean changes of the PANSS scores or the CGI scale scores between the treatment groups. Side effects varied widely among the groups. Weight gain of at least 7 lb occurred most frequently with combination treatment (39%), clozapine (32%), and olanzapine (23%). Highest exposure-adjusted blood glucose increases were seen with aripiprazole, and risperidone caused
Citrome et al ⁴⁶ Asenapine 5 to 10 mg twice daily vs atypical antipsychotics (olanzapine 5 to 20 mg daily, risperidone 3 mg twice daily) vs placebo	SR Phase II or III clinical studies of asenapine in adult patients with schizophrenia and bipolar mania	Schizophrenia (N=1,778); Bipolar mania (N=473) 3 to 52 weeks	Primary: NNH, NNT Secondary: Not reported	Primary: The NNT for a positive response with asenapine (defined as a minimum of 20% decrease in the PANSS total scores) vs placebo was 6. The NNT of 8 was calculated with asenapine vs placebo for a 30% reduction from baseline in PANSS total scores. For the patients with schizophrenia, the NNH values for asenapine vs placebo for commonly observed adverse reactions were 17 for somnolence, 34 for EPS, 34 for akathisia, and 25 for oral hypoesthesia. For patients with bipolar disorder, the NNH values for asenapine vs placebo were 6 for somnolence, 13 for dizziness, 20 for EPS other than akathisia and 25 for increased weight. In schizophrenia trials, the NNH for weight gain of at least 7% from baseline were 35, 14, and 9 in asenapine, risperidone, and olanzapine groups, respectively.

Souza et al (abstract) ²⁷¹ Olanzapine, doses not reported vs clozapine, doses not reported	MA Patients with treatment-resistant schizophrenia	N=648 Duration not reported	Primary: Dropout rates, PANSS scales Secondary: Not reported	In schizophrenia trials, the NNH for fasting glucose level 1.5 times the upper limit of normal were 452, 188, and 174 in asenapine, risperidone, and olanzapine groups, respectively. In schizophrenia trials, the NNH for LDL cholesterol >50% upper limit of normal were 234 and 174 in asenapine and olanzapine groups, respectively. The NNH for prolactin level over 4 times the upper limit of normal were 19, 4, and 33 in asenapine, risperidone, and olanzapine groups, respectively. Secondary: Not reported Primary: Olanzapine and clozapine had similar effects on dropout rates (RR, 0.93; 95% CI, 0.77 to 1.12), PANSS total endpoints (SMD, 0.21; 95% CI, -0.04 to 0.46) and PANSS total mean changes (SMD, 0.08; 95% CI, -0.01 to 0.027). Clozapine was "superior" to olanzapine for PANSS positive (SMD, 0.51; 95% CI, 0.17 to 0.86) and negative (SMD, 0.50; 95% CI, 0.16 to 0.85) subscales. Secondary: Not reported
Glick et al ⁴⁷ Atypical antipsychotics (olanzapine, risperidone,	MA Randomized, double-blind	N=not reported at least 3	Primary: PANSS total score, relapse rate, discontinuation	Primary: Compared to placebo, olanzapine was associated with the greatest improvement in PANSS total scores from baseline, followed by risperidone (P>0.05), quetiapine (P=10 ⁻⁴) and ziprasidone (P=0.004).
quetiapine, aripiprazole, ziprasidone, clozapine) vs	studies with atypical antipsychotics in patients with	months	rate, adverse events Secondary:	Compared to olanzapine, the following risk ratios [RR] for relapse were determined: 0.87 for risperidone, 0.55 for ziprasidone and 0.39 for quetiapine (P value not reported).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
placebo	schizoaffective disorder		Not reported	Compared to olanzapine, the following hazard ratios [HR] for relapse were determined: 0.84 for risperidone, 0.78 for ziprasidone and 0.60 for quetiapine (P value not reported). Compared to olanzapine, the following hazard ratios for all-cause discontinuations were determined: 0.77 for risperidone (P=0.005), 0.71 for quetiapine (P=0.02) and 0.68 for ziprasidone (P<0.001). Compared to olanzapine, the following hazard ratios for discontinuation due to poor efficacy were noted in the EUFEST study: 0.39 for ziprasidone (P<0.001) and 0.34 for quetiapine (P<0.001). Conclusion: Clozapine is the most effective atypical antipsychotic. Olanzapine is more effective than risperidone; though both are more effective compared to the other atypical antipsychotics. EPS as measured by the use of antiparkinson drugs and compared to placebo were greatest in association with ziprasidone, followed by risperidone, olanzapine, aripiprazole and finally quetiapine (P value not reported). Akathisia as measured by the use of antiparkinson drugs and compared to olanzapine was most frequent in association with risperidone, followed by aripiprazole, olanzapine, ziprasidone and finally quetiapine (P value not reported). Weight gain, compared to olanzapine, was greatest in association with clozapine and olanzapine (comparable), followed by risperidone and quetiapine (2-4 lb weight gain), and least with ziprasidone and aripiprazole (P value not reported). Aripiprazole and ziprasidone caused approximately 4 kg less weight gain compared to olanzapine. Risperidone and quetiapine caused approximately 2.5-3 kg less weight gain compared to olanzapine.

Jones et al ⁴⁸ Atypical antipsychotics (risperidone 4-8 mg daily, aripiprazole 10-30 mg daily, olanzapine 10-20 mg daily, quetiapine 150-750 mg daily, paliperidone ER 3-12 mg			Primary: PANSS, CGI-S scores, discontinuation rate, adverse events Secondary:	Secondary: Not reported Primary: All of the atypical antipsychotic drugs significantly improved total PANSS scores from baseline, compared to placebo (overall effect size -11.6; 95% CI, -13.3 to -10.0). Effect sizes (ES) for the individual agents ranged from -14.9 (95%CI, -17.6 to -12.3) for olanzapine to -9.5 (95%CI, -11.7 to -7.2) for aripiprazole. All of the atypical antipsychotic drugs were associated with a significant
daily) vs placebo			Not reported	improvement in PANSS positive scores from baseline compared to placebo (overall ES, -3.7; 95%CI, -4.2 to -3.1). Effect sizes for individual agents ranged from -4.3 for risperidone and olanzapine (risperidone: 95%CI, -5.7 to -2.8 and olanzapine: 95%CI, -5.3 to -3.4) to -2.6 (95%CI, -3.4 to -1.7) for aripiprazole. All of the atypical antipsychotic drugs were associated with a significant improvement in PANSS negative scores compared to placebo (overall effect size, -2.4, 95%CI, -2.9 to -2.0). Effect sizes for individual agents ranged from -3.4 (95%CI, -4.2 to -2.7) for olanzapine to -1.3 (95%CI, -2.6 to -0.07) for quetiapine.
				Improvement on CGI-S score with atypical antipsychotic agents was -0.5 overall (95%CI, -0.6 to -0.4). Effect sizes for individual agents ranged from -0.8 (95%CI, -1.1 to -0.5) for risperidone to -0.3 (95%CI, -0.4 to -0.2) for aripiprazole. Paliperidone ER, olanzapine and risperidone tended to have lower discontinuation rates due to lack of efficacy compared to all atypical antipsychotics combined. Whereas, discontinuation rates tended to be greater among patients receiving aripiprazole and quetiapine compared to the mean rate for the atypical antipsychotics (P value not reported). There was no significant difference in discontinuation rates due to adverse events for all the atypical antipsychotic agents combined

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				compared to placebo. Results were similar for the individual agents except olanzapine, which had a higher discontinuation rate due to adverse effects.
				Atypical antipsychotics were associated with significant weight gain compared to placebo (OR, 2.84; 95%CI, 2.3 to 3.5). Odds of weight gain were lowest with paliperidone ER (OR, 1.75; 95%CI, 1.29 to 2.37) and highest with olanzapine (OR, 4.56; 95%CI, 3.46 to 6.01).
				Atypical antipsychotics were associated with increased odds of somnolence compared to placebo (OR, 1.7; 95%CI, 1.39 to 2.09). Odds of somnolence were lower than the mean with paliperidone ER and aripiprazole and higher than the mean with risperidone and olanzapine.
				Overall, there was no significant difference in agitation between atypical antipsychotics and placebo. Agitation tended to be lower than placebo for paliperidone ER and for quetiapine, but the significance of the result was uncertain.

first generation antipsychotics as comparator agents (including chlorpromazine, fluphenazine, haloperidol, perphenazine, thioridazine, thiothixene, trifluoperazine, plus others not available in the United States)		accepted optimal doses of each antipsychotic Duration of studies varied (from ≤12 weeks to >6 months)		negative symptoms. Aripiprazole, quetiapine, sertindole, ziprasidone, and zotepine were not more effective than first-generation agents for treatment of negative symptoms. Aripiprazole, quetiapine, sertindole, ziprasidone, and zotepine were no more efficacious than first-generation agents for positive symptoms (and quetiapine was less efficacious). Amisulpiride, aripiprazole, clozapine, olanzapine, and quetiapine were significantly better in treating depressive symptoms than first-generation agents, whereas risperidone was not. Olanzapine, risperidone, and sertindole were found to be significantly better than first-generation agents in preventing relapse; amisulpiride, aripiprazole, and clozapine showed no significant difference (no studies were available for the other second-generation agents). Only amisulpiride, clozapine, and sertindole were better than first-generation agents for improving quality of life (which was reported in only 17 studies). All second-generation antipsychotics were associated with much fewer EPS effects than haloperidol. Amisulpiride, clozapine, olanzapine, quetiapine, risperidone, sertindole, and zotepine were associated with significantly more weight gain than haloperidol, whereas aripiprazole and ziprasidone were not. Clozapine, quetiapine, and zotepine were significantly more sedating than was haloperidol, whereas aripiprazole was significantly less sedating.

Fewer patients in the olanzapine group left the study early due to inefficacy of treatment compared to quetiapine (RR, 0.56; 95%CI, 0.44 to 0.70, NNT=11), risperidone (RR, 0.78; 95%CI, 0.62 to 0.98, NNT=50 and ziprasidone (RR, 0.64; 95%CI, 0.51 to 0.79, NNT=17). Significantly fewer patients left the study early due to adverse events in the olanzapine group compared to clozapine (RR, 0.62; 95%CI, 0.43 to 0.92, NNT=20). Fewer patients required re-hospitalization in the olanzapine group
	inefficacy of treatment compared to quetiapine (RR, 0.56; 95%CI, 0.44 to 0.70, NNT=11), risperidone (RR, 0.78; 95%CI, 0.62 to 0.98, NNT=50 and ziprasidone (RR, 0.64; 95%CI, 0.51 to 0.79, NNT=17). Significantly fewer patients left the study early due to adverse events in the olanzapine group compared to clozapine (RR, 0.62; 95%CI, 0.43 to 0.92, NNT=20).
	patients left the study early due to adverse events in the olanzapine group compared to clozapine (RR, 0.62; 95%CI, 0.43 to 0.92, NNT=20).
	Fewer nationts required to hospitalization in the clanzanine group
	compared to quetiapine (RR, 0.56; 95%CI, 0.41 to 0.77; NNT=11) and ziprasidone (RR, 0.65; 95%CI, 0.45 to 0.93; NNT=17); whereas, more
	patients in the olanzapine group were re-hospitalized compared to the clozapine group (RR, 1.28; 95%CI, 1.02 to 1.61, NNH not estimable).
	Except for clozapine, all comparators caused less weight gain than olanzapine (vs aripiprazole: WMD, 5.60kg, 95%Cl, 2.15kg to 9.05kg; vs quetiapine: WMD, 2.68kg, 95%Cl, 1.10kg to 4.26kg; vs risperidone: WMD, 2.61kg, 95%Cl, 1.48kg to 3.74kg; vs ziprasidone: WMD, 3.82kg,
	95%CI, 2.96kg to 4.69kg). Metabolic side effects such as glucose and cholesterol level increases
	were also more frequent in the olanzapine group compared to most comparators.
	Olanzapine may be associated with more EPS side effects than quetiapine, assessed by the use of antiparkinson medication (RR, 2.05; 95%CI, 1.26 to 3.32, NNH=25), but less than risperidone (RR, 0.78; 95%CI, 0.65 to 0.95, NNH=17) and ziprasidone (RR, 0.70;95%CI, 0.50 to 0.07, NNH, not estimable)
	0.97, NNH not estimable). Olanzapine may increase prolactin level to a greater degree than aripiprazole, clozapine and quetiapine, but considerable less so than risperidone (WMD, -22.84; 95%CI, -27.98 to -17.69).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
Komossa et al ⁵³	SR	N=4101	Primary:	There was no significant difference between olanzapine and aripiprazole, ziprasidone or risperidone groups in change in QTc interval from baseline. Quetiapine was associated with significantly increased QTc interval from baseline, compared to olanzapine. Secondary: Not reported Primary:
Quetiapine, doses ranged from 50 to 800 mg daily	Randomized, at least single-blind design, comparing	(21 studies) 2 to 12 weeks	Leaving the study early, PANSS, adverse events	Quetiapine was less effective in improving the general mental state (PANSS total score) compared to olanzapine (WMD, 3.66; 95%CI, 1.93 to 5.39) and risperidone (WMD, 3.09; 95%CI, 1.01 to 5.16). There were no significant differences in PANSS total scores between quetiapine and
vs clozapine, doses not reported	oral quetiapine with oral forms of clozapine,		Secondary: Not reported	either clozapine or ziprasidone. Compared to olanzapine, quetiapine was associated with fewer
vs	olanzapine, risperidone or ziprasidone in			movement disorders, assessed via the use of antiparkinson medication (RR, 0.49; 95%CI, 0.3 to 0.79, NNH=25 CI) and less weight gain (WMD, -2.81; 95%CI, -4.38 to -1.24) and glucose elevation (WMD, -9.32;
olanzapine, doses not reported	people with schizophrenia or schizophrenia-like			95%CI, -17.82 to -0.82), but more QTc prolongation (WMD, 4.81; 95%CI, 0.34 to 9.28). There was no significant difference in sedation between olanzapine and quetiapine. Likewise, cholesterol level changes from
vs	psychosis			baseline were comparable between the groups.
risperidone, doses not reported				Compared to risperidone, quetiapine was associated with fewer movement disorders, assessed via the use of antiparkinson medication (RR, 0.5; 95%CI, 0.3 to 0.86; NNH=20), less prolactin increase (WMD,
vs				-35.28; 95%CI, -44.36 to -26.19) and some related adverse effects, but more cholesterol increase (WMD, 8.61; 95%CI, 4.66 to 12.56).
ziprasidone, doses not reported				Quetiapine was associated with significantly more sedation (RR, 1.21; 95%CI, 1.06 to 1.38; NNH=20), compared to risperidone. There was no significant difference in weight gain between the groups.
				Compared to ziprasidone, quetiapine was associated with fewer EPS adverse effects, assessed via the use of antiparkinson medication (RR,

Suttajit et al ²⁷³	SR	N=7,217	Primary:	0.43; 95%CI, 0.2 to 0.93, NNH not estimable) and prolactin increase. However, quetiapine was associated with significantly more sedation (RR, 1.36; 95%CI, 1.04 to 1.77; NNH=14) and weight gain (RR, 2.22; 95%CI, 1.35 to 3.63; NNH=13) and cholesterol (WMD, 16.01; 95%CI, 8.57 to 23.46) compared to ziprasidone. There was no significant difference in QTc prolongation between the groups. Secondary: Not reported The proportion of patients leaving the studies was not significantly
Quetiapine, dose not reported vs typical antipsychotics Typical antipsychotics were considered any other antipsychotic excluding Amisulpride*, sulpiride*, zotepine*, olanzapine, risperidone, sertindole*, aripiprazole, ziprasidone and clozapine, at any dose.	Randomized, blinded studies comparing quetiapine typical antipsychotics in patients with schizophrenia or schizophrenia-like psychosis	(43 studies) Duration not reported	Global state Secondary: Leaving study early, relapse, mental state (positive and negative symptoms), general functioning, quality of life, cognitive function, service use (hospitalizations) and adverse events	different between patients reated with quetiapine or typical antipsychotics (36.5 vs 36.9%, respectively; RR, 0.91; 95% CI, 0.81 to 1.01). Fewer patients treated with quetiapine left the studies early due to adverse events (RR, 0.48; 95% CI, 0.30 to 0.77). Overall, global state was not significantly different between patients treated with quetiapine or typical antipsychotics (RR, 0.96; 95% CI, 0.75 to 1.23) and there was no significant difference in positive symptoms (PANSS positive subscore; MD, 0.02; 95% CI, -0.39 to 0.43). Similarly, general psychopathology was similar between the treatments (PANSS general psychopathology subscore; MD, -0.20; 95% CI, -0.83 to 0.42). Quetiapine treatment was significantly more effective for negative symptoms (PANSS negative subscore; MD, -0.82; 95% CI -1.59 to -0.04); however, this result was highly heterogeneous and driven by two small outlier studies with high effect sizes. Without these two studies, there was no heterogeneity and no statistically significant difference between quetiapine and typical antipsychotics. Quetiapine treatment may be associated with fewer adverse events (RR, 0.76; 95% CI, 0.64 to 0.90; NNH, 10), less abnormal ECG (RR, 0.38; 95% CI, 0.16 to 0.92; NNH, 8), fewer overall EPS effects (RR, 0.17; 95% CI, 0.09 to 0.32; NNH 3) and fewer specific EPS effects including akathisia, parkinsonism, dystonia and tremor.

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
Komossa et al ⁵⁴	SR	N=7,760	Primary:	Quetiapine may be associated with lower prolactin level (MD, -16.20; 95% CI, -23.34 to -9.07) and less weight gain compared to some typical antipsychotics in the short term (RR, 0.52; 95% CI, 0.34 to 0.80; NNH, 8). There was no significant difference between the two groups in suicide attempt, suicide, death, QTc prolongation, low blood pressure, tachycardia, sedation, gynecomastias, galactorrhea, menstrual irregularity and white blood cell count. Primary:
Risperidone, doses ranged from 0.5 to 12 mg daily vs amisulpride*, doses ranged from 100 to 1000 mg daily	Randomized, blinded studies comparing risperidone with oral forms of amisulpride, clozapine,	up to 12 weeks (31 studies); 13-26 weeks (6 studies); >26 weeks (8 studies)	Leaving the study early, CGI, PANSS, BPRS, Quality of Life Scale (QLS), adverse events Secondary: Not reported	Based on data from two studies, compared to aripiprazole, risperidone was not associated with a significant change in global state, measured on the CGI scale (RR, 0.88; 95%CI, 0.62 to 1.24). There was no significant difference between risperidone and aripiprazole groups in leaving the study early (35 vs 34%; RR, 1.06; 95%CI, 0.79 to 1.41). Moreover, there was no significant difference between risperidone and aripiprazole groups in the mental state change from baseline, as measured on the PANSS total, negative and positive scales.
vs aripiprazole, doses ranged from 15 to 30 mg daily vs clozapine, doses ranged from 25 to 900 mg daily	olanzapine, quetiapine, or ziprasidone in patients with schizophrenia or schizophrenia-like psychosis	Studies)		Compared to clozapine, risperidone was not associated with a significant change in global state, measured on the CGI scale (RR, 1.07; 95%CI, 0.88 to 1.30). While the overall percentage of patients leaving the study early did not significantly differ between risperidone and clozapine groups (35 vs 31%; RR, 1.10; 95%CI, 0.86 to 1.41), risperidone was associated with a significantly greater discontinuation rate due to inadequate efficacy (14 vs 5%), but with a significantly lower rate of discontinuations due to side effects (7 vs 12%), compared to clozapine. There were no significant differences between groups in the changes from baseline in PANSS total scores (a measure of mental state), BPRS scores, positive and negative PANSS subscale scores, GAF scores of general functioning, or cognitive functioning scores.
olanzapine, doses ranged from 2.5 to 40 mg daily				functioning scores. Compared to olanzapine, risperidone was not associated with a significant change in global state, measured on the CGI scale (RR, 0.98; 95%CI, 0.88 to 1.09). Fewer patients receiving olanzapine left the study early than patients in the risperidone group (48 vs 56%; RR, 1.14; 95%CI,

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
quetiapine, doses ranged from 50 to 800 mg daily vs ziprasidone, doses ranged from 40 to 160 mg daily	Demographics	Duration		1.07 to 1.21; NNH=13). There was a trend in more patients leaving in the risperidone group due to inadequate efficacy. Olanzapine therapy was associated with significantly greater improvement in the PANSS total scores (MD, 1.94; 95%Cl, 0.58 to 3.31), negative symptoms as reflected by the SANS total scores (MD, 1.40; 95%Cl, 0.37 to 2.43), and QLS total scores (MD, 5.10; 95%Cl, 1.09 to 9.1). The percentage of patients leaving the study early did not significantly differ between risperidone and quetiapine groups (54 vs 57%; RR, 0.94; 95%Cl, 0.87 to 1.02). Risperidone was associated with greater efficacy in the following outcome measures: PANSS total score (MD, -3.09; 95%Cl, -5.16 to -0.40), PANSS positive scores (MD, -1.82; 95%Cl, -2.48 to -1.16), BPRS positive scores (MD, -1.10; 95%Cl, -2.02 to -0.18) and BPRS negative scores (MD, -0.57; 95%Cl, -0.97 to -0.17). Based on date from three studies, the percentage of patients leaving the study early did not significantly differ between risperidone and ziprasidone groups (58 vs 65%; RR, 0.90; 95%Cl, 0.83 to 0.98). Risperidone was associated with greater efficacy in the following outcome measures: PANSS total score (MD, -3.91; 95%Cl, -7.55 to -0.27) and PANSS positive scores (MD, -2.50; 95%Cl, -4.62 to -0.38). There were no significant differences between groups in the other efficacy endpoints. Risperidone produced more EPS side effects than a number of other atypical antipsychotics (use of antiparkinson medication vs clozapine RR, 2.57, 95%Cl, 1.47 to 4.48, NNH=6; vs olanzapine RR, 1.28, 95%Cl, 1.06 to 1.55, NNH=17; vs quetiapine RR, 1.98, 95%Cl, 1.16 to 3.39, NNH=20; vs ziprasidone RR, 1.42; 95%Cl, 1.03 to 1.96, NNH not estimable). Risperidone increased prolactin levels significantly more than all comparators (vs aripiprazole, MD, 54.71, 95%Cl, 49.36 to 60.06; vs clozapine, MD, 38.50, 95%Cl, 23.30 to 53.70; vs olanzapine, MD, 22.84; 95%Cl, 17.69 to 27.98; vs quetiapine, MD, 35.28; 95%Cl, 26.19 to 44.36; vs ziprasidone, MD, 21.97; 95%Cl, 16.60 to 27.34).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				There were no significant differences between risperidone and aripiprazole in glucose level or ECG changes. There were no significant differences between risperidone and olanzapine in ECG changes, glucose level, or seizures. There was no significant difference between risperidone and ziprasidone in ECG changes from baseline.
				Sedation (NNT=5) and seizures (NNT=14) occurred significantly less often with risperidone compared to clozapine. Sedation and somnolence occurred significantly less often with risperidone than with quetiapine (NNT=20 and NNT=13, respectively). Sedation was comparable between risperidone and the other drug comparisons.
				Risperidone was associated with significantly less weight gain compared to clozapine (MD, -3.30; 95%CI, -5.65 to -0.95) and olanzapine (MD, -0.61; 95%CI, -3.74 to -1.48). There were no significant differences in weight gain between risperidone and aripiprazole or quetiapine. Risperidone was associated with significantly more weight gain of >7% of total body weight compared to ziprasidone (RR, 2.03; 95%CI, 1.35 to 3.06; NNH=14).
				Risperidone was associated with greater increases in cholesterol levels compared to aripiprazole (MD, 22.30; 95%Cl, 4.91 to 39.69) and ziprasidone (MD, 8.58; 95%Cl,1.11 to 16.04), but less than olanzapine (MD -10.36; 95% Cl -14.43 to -6.28) and quetiapine (MD, -8.49; 95%Cl, -12.23 to -4.75). Secondary: Not reported
Komossa et al ⁵⁵	SR	N=3361	Primary:	Primary:
Ziprasidone, doses ranged from 40 to 160 mg daily	Randomized, at least single-blind studies comparing	18 to 78 weeks	Leaving the study early, PANSS, BPRS, Quality of Life Scale (QLS),	Based on one study comparing ziprasidone with clozapine, the two drugs were not shown to be significantly different in the number of patients leaving the study early due to any reason (RR, 1.0; 95%CI, 0.66 to 1.51). There was no significant difference between clozapine and ziprasidone in
vs	ziprasidone with oral forms of		adverse events	PANSS total score reduction from baseline (P value not reported).

amisulpride*, doses not reported vs clozapine, doses not reported vs olanzapine, doses not reported vs quetiapine, doses not reported	amisulpride, clozapine, olanzapine, quetiapine, or risperidone in patients with schizophrenia or schizophrenia-like psychosis		Secondary: Not reported	Ziprasidone was a less acceptable treatment than olanzapine based on leaving the study early for any reason (RR, 1.26; 95%CI, 1.18 to 1.35; NNH=7). There was no significant difference between the groups in leaving the study early due to adverse events (RR, 1.12; 95%CI, 0.77 to 1.61), while olanzapine was preferred over ziprasidone in terms of leaving the study early due to inadequate efficacy (RR, 1.57; 95%CI, 1.27 to 1.94). Ziprasidone was less efficacious than olanzapine in the PANSS total score reduction from baseline (MD, 8.32 CI 5.64 to 10.99) and the positive PANSS subscore (RR, 3.11; 95%CI, 1.93 to 4.30). There were no significant changes between ziprasidone and olanzapine groups in BPRS total score, negative PANSS subscore, or the QLS total score. Based on the data from two studies comparison ziprasidone with quetiapine, there were no statistically significant differences between the groups in leaving the study early for any reason, improvement in PANSS total score, changes in PANSS positive and negative subscales (P value not reported).
vs risperidone, doses not reported				Ziprasidone was a less acceptable treatment than risperidone based on leaving the study early for any reason (RR, 1.11; 95%CI, 1.02 to 1.20; NNH=14), but not different from the other atypical antipsychotic drugs. Ziprasidone was less efficacious compared to risperidone in terms of improvement in PANSS total score from baseline (MD, 3.91; 95%CI, 0.27 to 7.55). PANSS positive subscale scores were significantly improved with risperidone compared to ziprasidone (MD, 2.50; 95%CI, 0.38 to 4.62); though there was no significant difference between the groups in the PANSS negative subscale score changes from baseline (MD, 0.04; 95%CI, -1.12 to 1.20). Neither was there a significant difference between groups in the BPRS total score (MD, 0.70; 95%CI, -2.93 to 4.33). Based on limited data there were no significant differences in tolerability between ziprasidone and amisulpride or clozapine. There were no significant differences between ziprasidone and olanzapine in the risk of QTc interval prolongation (MD, 2.19; 95%CI, -

placebo			prolactin increase, QTc prolongation, and sedation	(SMD, -0.38; 95% CI, -0.51 to -0.25), lurasidone (SMD, -0.33; 95% CI, -0.45 to -0.21) and iloperidone (SMD, -0.33; 95% CI, -0.43 to -0.22).
			and Sedation	Secondary: All-cause discontinuation was significantly better with antipsychotics compared to placebo, with the exception of zotepine. The ORs and NNTs ranged from 0.43 and 6 for amisulpride to 0.80 and 20 for haloperidol. Amisulpride (range of significant mean ORs 0.53 to 0.71; NNT 8 to 14), olanzapine (ORs, 0.58 to 0.76; NNT, 9 to17), clozapine (ORs, 0.57 to 0.67; NNT 9 to 12), paliperidone (ORs, 0.60 to 0.71; NNT 9 to 14), and risperidone (OR, 0.66 to 0.78; NNT 11 to 18) had significantly lower all-cause discontinuation compared to several other drugs. Haloperidol was worse than quetiapine (OR, 1.32; NNT,15) and aripiprazole (OR, 1.33; NNT, 15).
				Other than haloperidol, ziprasidone and lurasidone, all antipsychotics produced more weight gain compared to placebo. Olanzapine produced significantly more weight gain than most other drugs (SMD, 0.74; 95% CI, 0.67 to 0.81), followed by zotepine (SMD, 0.71 95% CI, 0.47 to 0.96). Clozapine (SMD, 0.65; 95% CI, 0.31 to 0.99), iloperidone (SMD, 0.62; 95% CI, 0.49 to 0.74), chlorpromazine (SMD, 0.55; 95% CI, 0.34 to 0.76), sertindole (SMD, 0.52; 95% CI, 0.38 to 0.68), quetiapine (SMD, 0.43; 95% CI, 0.34 to 0.53), risperidone (SMD, 0.42; 95% CI, 0.33 to 0.50), and paliperidone (SMD, 0.38; 95% CI, 0.27 to 0.48) produced significantly more weight gain than haloperidol, ziprasidone, lurasidone, aripiprazole, amisulpride, and asenapine (with the exception that asenapine did not differ significantly from paliperidone). Other differences were not statistically significant apart from iloperidone causing more weight gain than paliperidone, risperidone, and quetiapine.
				Clozapine, sertindole, olanzapine, quetiapine, aripiprazole, iloperidone, amisulpride and asenapine did not cause significantly more EPS adverse

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				events compared to placebo. Clozapine produced fewer EPS adverse events compared to all other drugs and placebo, and was followed in ranking by sertindole, olanzapine, and quetiapine. Haloperidol caused significantly more EPS adverse events compared to other drugs apart from zotepine and chlorpromazine. Zotepine, chlorpromazine, lurasidone, risperidone, and paliperidone were among the least well tolerated drugs, because they produced significantly more EPS adverse events compared to several other antipsychotics. Aripiprazole, quetiapine, asenapine, chlorpromazine and iloperidone did not cause significantly increased prolactin concentrations compared to placebo. Paliperidone and risperidone were associated with significantly more prolactin increase than all other drugs including haloperidol. Lurasidone, aripiprazole, paliperidone, and asenapine were not associated with significantly greater QTc prolongation compared to placebo. The greatest risk of QTc prolongation occurred with sertindole, amisulpride, ziprasidone and iloperidone. Amisulpride, paliperidone, sertindole and iloperidone were not significantly more sedating compared to placebo. The greatest risk of sedation occurred with clozapine, followed by zotepine, chlorpromazine, ziprasidone, quetiapine, olanzapine, asenapine, haloperidol, risperidone,
Crespo-Facorro et al ²⁷⁹	OL, PRO, RCT	N=174	Primary:	lurasidone and aripiprazole. Primary:

	disorder, schizophrenia, or schizoaffective disorder		Secondary: Mean change in BPRS, SAPS and SANS, CGS, YMRS, and CDSS total scores at 3 months and the UKU rating scale	rate differences (χ²=20.223; P<0.001). The mean time (days) to all-cause discontinuation was 37.39 (95% CI, 27.71 to 47.07) for aripiprazole, 38.26 (95% CI, 29.19 to 47.33) for ziprasidone and 35.92 (95% CI, 28.44 to 43.40) for quetiapine. There was a significant difference between groups in time to discontinuation (Log Rank=23.467, P<0.001). Secondary: There were no statistically significant differences in the severity of symptoms at baseline and at three months between the treatment groups. The univariate ANOVA analysis, after controlling by CDSS total score at baseline, also showed differences between treatments in reducing depressive symptoms (F=4.404; P=0.014). The post hoc pairwise analysis revealed a lower effect of ziprasidone compared to aripiprazole and quetiapine. The rate of responders (≥ 40%BPRS & ≤ 4 CGI) differed between groups (aripiprazole, 76.4%; ziprasidone, 55.8%; quetiapine 64.6%; F=5.950; P=0.051). This difference in the rate of responders between groups was statistically significant when the criteria of at least a 50% decrease in total BPRS at baseline was used as a cutoff (aripiprazole, 61.1%; ziprasidone, 36.5%; quetiapine, 50.0%; F=7.303; P=0.026). Intention-to-treat analyses showed no significant differences in the increment of extrapyramidal signs at three months (SARS total score) between treatments (F=1.513; P=0.223). The percentage of patients with treatment-emergent parkinsonism (a total score higher than three on the SARS at 6-weeks or/and 3-month assessments, given a total score of three or less at baseline) was not statistically different between treatment arms (aripiprazole, 13.9%; ziprasidone, 15.4%; quetiapine, 4.0%; χ²=3.940; P=0.139), although it could be of clinical relevance. Extrapyramidal signs were more severe and more frequent with aripiprazole and ziprasidone than with quetiapine. There was no significant difference between treatments in the severity of akathisia (BAS total score) at three months assessment (F=2.616; P=0.076). It is of note that a higher numbe

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				aripiprazole- and ziprasidone-treated groups (25.0% in both groups) experienced treatment-emergent akathisia (BAS global score of 2 or more at 6-week or/and 3-month evaluations, given a global score of less than 2 at baseline visit) compared to quetiapine-treated subjects (8.0%) (χ^2 =6.408; P=0.041).
				Intention-to-treat analyses revealed that quetiapine showed a marked increase in the prevalence of treatment-emergent somnolence (quetiapine, 34.0%; ziprasidone, 15.4%; and aripiprazole, 16.7%) (χ 2=6.827; P=0.033) and an increased duration of sleep (quetiapine, 12.0%; ziprasidone, 3.8%; and aripiprazole, 1.4%) (χ 2=7.040; P=0.03). Significant differences were also found in the frequency of body weight increase between treatments (χ 2=11.551; P=0.003). One individual on ziprasidone (1.6%) showed a body weight increase compared to 23.6% of patients on aripiprazole and 14.0% of patients on quetiapine.
				Patients on quetiapine were taking significantly less hypnotics (lormetazepam) at the three month assessment compared to those patients on aripiprazole and ziprasidone (12.0%, quetiapine; 32.7% ziprasidone; 22.2%, aripiprazole; χ^2 =6.279; P=0.043). No significant differences were found between groups in the rate of anti-muscarinic agents, benzodiazepines, mood stabilizers and antidepressant use at three months.
Sanz-Fuentenebro et al ²⁸⁰	AC, MC, RCT	N=30	Primary:	Primary:
Risperidone dose adjusted (2 to 10 mg once daily)	Patients <35 (males) or <40	12 months	Time to treatment, change in PANSS and UKU Side Effect Rating Scale	Patients initially assigned to clozapine remained on this treatment for a significantly longer period of time (41.1 ± 15.9 weeks) than those initially assigned to the risperidone arm (23.3 ± 20.1 weeks; U=58, Z=2.44, P=0.015). Upon reaching the end of the 12 th month, the number of cases
VS	(females) years of		at LOCF and at 12 months, and	with the same treatment prescribed initially (including drop-outs and
clozapine dose adjusted (12.5 to 900 mg once daily)	age with a primary diagnosis of schizophrenia or schizophreniform disorder, absence		weight, glycemia and cholesterol changes	switches) was higher for clozapine (9 out of 15) than for risperidone (5 out of 15). However, this difference was not statistically significant (χ^2 =1.13, df=1, P=0.13). If adherence to treatment after one year was considered as the outcome variable, the NNT is 4.16.
	of any other		Secondary:	Clinical changes with both drugs were similar, although the improvement

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
	psychiatric disorder, absence of psychotropic drugs one month before start of study and absence of drug dependency (including alcohol; excluding nicotine and caffeine)		Not reported	was marginally better in the clozapine group by the time of the LOCF in positive (U=72, Z=1.65, P=0.10) and total scores (U=74, Z=1.61, P=0.10). Patients on clozapine significantly improved from baseline in positive (mean change ~14.4 ± 7.4, Z=~3.62, P< 0.001), general (mean change ~17.3 ± 12.4, tz=~3.53, P<0.001) and total (mean change ~35.5 ± 26.6, Z=~3.52, P< 0.001) PANSS scores. Risperidone-treated patients significantly improved from baseline in positive (mean change ~9.5 ± 7.21, Z=~2.84 P=0.004) and total (mean change ~17.1 ± 27.7, Z=2.13, P=0.03) PANSS scores. In the 12-month comparison, there were no significant differences in the percent of change between clozapine (N=9) and risperidone (N=5) treated patients that never switched from their original treatment. The clozapine group (N=9) displayed a significant decrease in positive (mean change ~17.3 ± 5.3, Z=~2.67, P=0.008), general (mean change ~22.7 ± 10.3, Z=~2.67, P=0.008) and total (mean change ~48.0 ± 24.7, Z=~2.66, P=0.008) scores, as well as a marginal decrease (mean change ~8.2 ± 10.3, Z=~1.66, P=0.09) in negative symptom scores. The same comparisons for the risperidone group (N=5) displayed a significant decrease in positive (mean change ~15.8 ± 6.0, Z=~2.03, P=0.04) and general (mean change ~15.2 ± 9.7, Z=~2.02, P=0.04) symptoms, and a non-significant increase in negative (mean change ~0.4 ± 9.52, Z=~0.27, P=0.78) PANSS scores. There were no significant differences in UKU scores at 12 months or by the time of the LOCF. In both groups, asthenia and somnolence were significantly more severe at LOCF than at baseline. In the clozapine group, concentration deficit and increased sleep time were also more severe at LOCF. In the between group comparisons, only increased sleep time was marginally more severe in the clozapine group (U=49.5, Z=2.34, P=0.087).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				(Spearman's rho=-0.70, P=0.01), and total (Spearman's rho=-0.71, P=0.009) symptom improvement at 12 months. That association was also significant in both risperidone and clozapine treated patients considered alone.
				Both groups showed significant weight gain from baseline to endpoint, as well as increase in glycemia and cholesterol. Nevertheless, these changes were not significantly different between groups.
				Secondary: Not reported
Naber et al ²⁸¹ (RECOVER)	OL, PG, PRO, RCT	N=798 12 months	Primary: SWN-K responder	Primary: The SWN-K responder rate at month six in the PP was 64.8% (136/210)

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				There were no significant differences between the groups in terms of mean SWN-K subscale scores (physical functioning, social integration, mental functioning, self-control, or emotional regulation) at month 12 (quetiapine ER, N=210; risperidone, N=227).
				At month six, the SWN-K remission rate was 54.2% (142/262) in the quetiapine ER group compared with 48.1% (137/285) in the risperidone group, with no significant difference between the treatment groups (difference in SWN-K remission rate, 2.9%; 95% CI, -5.7 to 11.5). At month 12, the SWN-K remission rate was 66.2% (139/210) in the quetiapine ER group, compared with 56.4% (138/227) in the risperidone group (difference in SWN-K remission rate, 6.3%; 95% CI, -3.6, 16.2). The mean (SD) change in CGI–SCH overall severity score from baseline to Month 12 was similar in both treatment groups: -1.5 (1.1) in the
				quetiapine ER group and -1.3 (1.2) in the risperidone group. In total, 83.4% of patients (176/211) were classed as improved for CGI–SCH overall severity in the quetiapine ER group, compared with 78.4% of patients (178/227) in the risperidone group. At Month 12, mean (SD) change from baseline in CGI–SCH severity score for depressive symptoms was -1.3 (1.2) in the quetiapine ER group and -0.8 (1.3) in the risperidone group. The percentage of patients classed as improved for CGI-SCH depressive symptoms was higher in the quetiapine ER group (144/211; 68.2%) than in the risperidone group (131/227; 57.7%: OR for treatment effect, 1.65; 95% CI, 1.01, 2.70). There were no differences between the treatment groups for mean change from baseline to Month 12 in CGI–SCH positive symptom scores (quetiapine ER, -1.3; risperidone, -1.4), negative symptom scores (quetiapine XR, -1.4; risperidone, -1.3) and cognitive symptom scores (quetiapine XR, -1.2; risperidone, -1.1).
				The mean (SD) change in CGI–SCH overall severity score from baseline to Month 12 was similar in both treatment groups: −1.5 (1.1) in the quetiapine XR group and −1.3 (1.2) in the risperidone group.

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				In total, 83.4% of patients (176/211) were classed as improved for CGI–SCH overall severity in the quetiapine ER group, compared with 78.4% of patients (178/227) in the risperidone group. At month 12, mean (SD) change from baseline in CGI–SCH severity score for depressive symptoms was –1.3 (1.2) in the quetiapine ER group and –0.8 (1.3) in the risperidone group. The percentage of patients classed as improved for CGI-SCH depressive symptoms was higher in the quetiapine ER group (144/211; 68.2%) than in the risperidone group (131/227; 57.7%: OR for treatment effect, 1.65; 95% CI, 1.01 to 2.70). There were no differences between the treatment groups for mean change from baseline to month 12 in CGI–SCH positive symptom scores, negative symptom scores and cognitive symptom scores. Patient quality of life, measured by the EQ-5D health profile, was similar for both treatment groups at month six and month 12. The mean (SD)
				change from baseline to month 12 in EQ-5D index score was 0.21 (0.25) in the quetiapine ER group and 0.16 (0.24) in the risperidone group. In terms of functional improvement at month 12, 8/211 patients (3.8%) in the quetiapine ER group and 7/227 patients (3.1%) in the risperidone group reported a real improvement in both occupational and residential status from baseline; 160/211 patients (75.5%) in the quetiapine ER group and 171/227 patients (75.3%) in the risperidone group reported being in stable state for occupational and residential status as recorded at baseline.

Other atypical antipsychotics could include: amisulpride*, aripiprazole, clozapine, olanzapine, risperidone, sertindole*, ziprasidone or zotepine*.	patients with schizophrenia and other types of schizophrenia-like psychosis	Long term (2 studies)	reference to the positive and negative symptoms of schizophrenia), general functioning, quality of life/satisfaction with treatment, cognitive function, service use, adverse effects	general mental state, positive symptoms or negative symptoms. Data from all studies measuring efficacy were potentially skewed and should be interpreted with caution. Quality of life was not measured and was not reported in these studies. Quetiapine compared to clozapine Five studies (N= 334) fell into this comparison. The overall rate of participants leaving studies early was remarkably low (8.4%) and showed no clear difference between groups. This finding was based on only two small (N=135), short-term trials, limiting any interpretation. No significant difference was noted in global state, general mental state or positive symptoms on the basis of studies of low-quality. A small reduction in negative symptoms was noted in those taking quetiapine, but this result must be interpreted with caution, as it was based on two small trials with low-quality evidence. Quality of life was not measured and was not reported in these studies. Quetiapine compared to olanzapine Fourteen studies (N=1,953) contributed data to this comparison. Fewer people in the olanzapine group compared with the quetiapine group left studies early for 'any reason' or because of 'inefficacy of treatment'. This finding suggests that olanzapine is a more acceptable treatment than quetiapine, at least in the confines of clinical trials. Nevertheless, the overall rate of premature study discontinuations was high (61.7%), limiting the validity of all other results. Quetiapine is probably slightly less effective than olanzapine in reducing general mental state symptoms according to studies of moderate-quality evidence. No significant difference was noted in the reduction of negative

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				symptoms or positive symptoms. The latter findings should be interpreted with caution; studies measuring negative and positive symptoms were of low and very low quality, respectively.
				The number of participants re-hospitalized was significantly higher in the quetiapine group. This may reflect a certain efficacy advantage of olanzapine.
				Adverse effects were reported as at least one adverse effect, cardiac effects, QTc abnormalities and an increase in serum cholesterol, serum glucose and serum prolactin, as well as associated side effects, death, extrapyramidal symptoms, the occurrence of sedation, seizures and weight gain. Among these adverse effects, a benefit for quetiapine was found for the use of antiparkinson medication (a proxy measure for extrapyramidal adverse effects), weight, glucose, prolactin increase, and some prolactin-associated adverse effects. On the other hand, a certain superiority of olanzapine was noted in terms of QTc. Overall, it seems that quetiapine may be more tolerable than olanzapine, but this is weighed against slightly less efficacy.
				Very limited data on the important outcomes for quality of life are available. Olanzapine may improve general functioning (GAF total score) to a greater extent than quetiapine. One study of moderate quality reported no difference in quality of life measures between olanzapine and quetiapine.
				Quetiapine compared to paliperidone Two studies (N=406) provided data on this comparison.
				The overall number of participants leaving the studies early was relatively low compared with other comparisons (14.0%). No significant difference was reported between groups or for reasons why participants left the studies.
				Paliperidone showed better efficacy than quetiapine in improving the

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				overall mental state score and in reducing positive and negative symptoms. However, this finding was based on only one small, short-term trial, thus limiting interpretation.
				In one small study, more participants reported at least one side effect while taking quetiapine compared with paliperidone. However, another study showed an advantage of quetiapine in terms of parkinsonian side effects, prolactin levels, sexual side effects and weight gain. Further studies are required to clarify the differences in adverse effect profiles between these two medications.
				Quetiapine compared to risperidone Nineteen studies (N=3,123) met the inclusion criteria for this comparison.
				No clear difference was evident in the number of participants leaving the studies early, suggesting a similar overall acceptability of quetiapine and risperidone. Nevertheless, the overall discontinuation rate was high (51.8%), thus limiting the interpretation of all other results.
				Differences in efficacy were found for the general mental state, positive symptoms and, on exclusion of an outlier, negative symptoms. Quetiapine was less effective than risperidone in these aspects of psychopathology. Nevertheless, the differences were small (e.g., only three points on the PANSS total score).
				Adverse effects were reported as at least one adverse effect, cardiac effects, cholesterol increase, changes in serum glucose, increase in prolactin level and associated side effects, death, extrapyramidal adverse effects, sedation, weight gain and white blood cell count. Among these, quetiapine was better than risperidone in various measures of extrapyramidal adverse effects and prolactin-associated. On the other hand, quetiapine was associated with increased sedation and cholesterol compared with risperidone. These differences in the adverse effect profile and the slightly lower efficacy of quetiapine may be weighed in drug selection.

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				Three studies of moderate quality assessed quality of life. Participants treated with quetiapine reported significantly higher quality of life scores than those treated with risperidone. Quetiapine compared to ziprasidone Two studies (N=722) provided data on this comparison. The overall number of participants leaving the studies early was very high (80.7%), clearly limiting the interpretation of any findings beyond the outcome of 'leaving the study early'. No significant difference was noted between groups, but the acceptability of both compounds seems to be poor. No significant difference in global state, general mental state or positive symptoms was noted in studies with evidence of very low (general state) or low (positive and negative symptoms). Adverse effects were reported as at least one adverse effect; cardiac effects; death; extrapyramidal side effects; changes in cholesterol, glucose and prolactin; the occurrence of sedation and weight gain. Quetiapine was advantageous in the use of antiparkinson medication and for prolactin levels, and two studies with moderate-quality evidence favored ziprasidone for weight gain and sedation.
Leucht et al ²⁸³ Oral antipsychotic medications flexible-dose	MA Patients with a diagnosis of schizophrenia or related disorders	N=43,049 (212 studies) 6 weeks (4 to 12 weeks used if 6 week data was unavailable)	Primary: Mean change in symptoms at end of the study Secondary: All-cause discontinuation, weight gain, use of	Quality of life was not measured in these studies. Primary: Most of the differences between drugs are gradual rather than discrete. All drugs had a greater effect compared to placebo (range of mean effect sizes -0.33 to -0.88), and clozapine was significantly more effective than all the other drugs. After clozapine, amisulpride, olanzapine, and risperidone were significantly more effective than the other drugs apart from paliperidone and zotepine. These effect sizes were small (range -0.11 to -0.33).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
	Demographics	Duration	antiparkinson drugs as a measure of extrapyramidal side-effects, prolactin increase, QTc prolongation, and sedation	Secondary: All-cause discontinuation was used as a measure of acceptability. All drugs were significantly better than placebo apart from zotepine. ORs and NNTs ranged from 0.43 and 6 for amisulpride to 0.80 and 20 for haloperidol. Amisulpride (range of significant mean ORs 0.53 to 0.71; NNTs 8 to 14), olanzapine (0.58 to 0.76; 9 to 17), clozapine (0.57 to 0.67; 9 to 12), paliperidone (0.60 to 0.71; 9 to 14), and risperidone (0.66 to 0.78; 11 to 18) had significantly lower all-cause discontinuation than several other drugs. Haloperidol was worse than quetiapine (OR 1.32; NNT 15) and aripiprazole (OR 1.33; NNT 15). Apart from haloperidol, ziprasidone, and lurasidone, all drugs produced more weight gain than placebo. Olanzapine produced significantly more weight gain than most other drugs, followed by zotepine. Clozapine, iloperidone, chlorpromazine, sertindole, quetiapine, risperidone, and paliperidone produced significantly more weight gain than haloperidol, ziprasidone, lurasidone, aripiprazole, amisulpride, and asenapine (with the exception that asenapine did not differ significantly from paliperidone). Standardized mean differences for these comparisons ranged from -0.18 to -0.57. Other differences were not statistically significant apart from iloperidone causing more weight gain than paliperidone, risperidone, and quetiapine. Clozapine, sertindole, olanzapine, quetiapine, aripiprazole, iloperidone, amisulpride, and asenapine did not cause significantly more extrapyramidal side-effects than placebo. The range of mean ORs and
				NNHs for the other drugs were 1.61 to 4.76 and 3 to 11, respectively. Clozapine produced fewer extrapyramidal side-effects than all other drugs and placebo (mean ORs 0.06 to 0.40; NNTs 5 to 9), and was followed in ranking by sertindole, olanzapine, and. Haloperidol caused significantly more extrapyramidal side-effects than the other drugs apart from zotepine and chlorpromazine, for which the differences were not significant (mean ORs 0.06 to 0.52; NNHs 5 to 11; in favor of other
				drugs). Zotepine, chlorpromazine, lurasidone, risperidone, and paliperidone were among the least well tolerated drugs, because they

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				produced significantly more extrapyramidal side-effects than several others in the analysis.
				Aripiprazole, quetiapine, asenapine, chlorpromazine, and iloperidone did not cause significantly increased prolactin concentrations compared with placebo. Paliperidone and risperidone were associated with significantly more prolactin increase than all other drugs including haloperidol, and haloperidol was associated with significantly more than the rest apart from chlorpromazine and sertindole. Clozapine and zotepine could not be included in the analysis, because the one direct comparison between them (i.e., with each other) was not linked with any other drug in the network (standardized mean difference –1.23, 95% CI, –1.8 to –0.64, in favor of clozapine; n=52). No usable data were available for amisulpride.
				Lurasidone, aripiprazole, paliperidone, and asenapine were not associated with significant QTc prolongation compared with placebo. The standardized mean differences of the other drugs compared with placebo ranged from marginal (0.11, haloperidol) to large (0.90, sertindole).
				Amisulpride, paliperidone, sertindole, and iloperidone were not significantly more sedating than placebo. For the other drugs compared with placebo, mean ORs and NNHs ranged from 1.84 and 10 (aripiprazole) to 8.82 and 2 (clozapine).
				Results for efficacy and extrapyramidal side-effects were robust against the sensitivity and meta-regression analyses. The most notable exceptions were that the relative efficacy of asenapine increased from the 13th to the seventh rank when placebo comparisons were removed. A large, failed study had driven its primary result, so asenapine was also more effective (ninth rank) when such trials were excluded. Haloperidol doses lower than 12 mg per day (or 7.5 mg per day) caused significantly fewer extrapyramidal side-effects than did higher doses, but still more than any other antipsychotic drug; for the efficacy outcome, lower doses of haloperidol did not significantly differ from higher doses. Doses of Chlorpromazine higher than 600 mg per day (or 500 mg per day) were

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
Kumar et al ²⁸⁴ Atypical antipsychotics (risperidone, olanzapine, quetiapine, ziprasidone, aripiprazole, amisulpiride, paliperidone, lurasidone and clozapine)	SR Randomized controlled studies that were DB and included patients 13 to 17 years of age with a diagnosis of schizophrenia or related disorders and were treated with atypical antipsychotics	N=1,112 (13 studies) 12 weeks (12 studies) 13 to 26 (one study)	Primary: Global state, clinical response, global functioning, adverse effects, service utilization outcomes Secondary: Global state, clinical response, social functioning, adverse effects, service utilization, economic outcomes and quality of life/satisfaction of care	associated with higher efficacy (sixth rank) than lower doses (14th rank), with little difference in extrapyramidal side-effects. Small studies tended to show higher efficacy of the active interventions compared with placebo (regression coefficient=1.31; 95% CI, 0.58 to 2.03). However this had only a small effect on the ranking of the treatments. None of the other meta-regression or sensitivity analyses led to any important changes in the efficacy and extrapyramidal side-effect hierarchies. Primary/secondary: Atypical antipsychotics compared to placebo (only short term) Global state as measured on the CGI-S showed no significant difference between olanzapine and placebo (1 RCT, N=107, RR 0.84, 95% CI, 0.65 to 1.10) with regard to the number of non-responders. The number of non-responders was not significantly different between participants receiving olanzapine and those given placebo (1 RCT, N=107, RR 0.84, 95% CI, 0.65 to 1.10). However, the number of non-responders receiving aripiprazole 10 mg/day was greater than the number given placebo (1 RCT, N=197, RR 0.72, 95% CI, 0.56 to 0.94). Significantly more people had weight gain > 7% of their baseline pretreatment weight in the group receiving olanzapine over placebo (1 RCT, N=107, RR 3.56, 95% CI, 1.14 to 11.11). The mean weight gain for the group of young people receiving olanzapine was 4.3 kg as compared with 0.1 kg (P<0.001) for the placebo group. Significantly more young people treated with olanzapine developed treatment-emergent serum high prolactin concentration at any time during treatment (81.0% vs 16.7%, P=0.008) as compared with the placebo group. The number of people with clinically significantly higher for the olanzapine group (1 RCT, N=107, RR 4.70, 95% CI, 2.25 to 9.82).
				In another study the authors reported no significant difference in weight gain > 5% between the group receiving aripiprazole and the group given placebo (1 RCT, N=202, RR 4.41, 95% CI, 0.98 to 19.91). Taken together, all adolescents treated in the aripiprazole arms of the trial, had

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				significantly lower serum prolactin concentration (1 RCT, N= 302, RR 3.77, 95% CI, 1.88 to 7.58) as compared with the placebo group.
				Significantly more (57% vs 32%) people left the study early (1 RCT, N=107, RR 0.56, 95% CI, 0.36 to 0.87) from the placebo group as compared with the olanzapine group. In the treatment arm, 10 of a total of 72 young people (14%) allocated to the olanzapine arm left the study because of lack of efficacy as compared with 18 of 35 young people (51%) allocated to the placebo arm, who left the study for the same reasons. In this trial, only 5 (7%) young people left the intervention arm (olanzapine) as the result of adverse effects. In the other study, no difference was noted between the intervention arm and the placebo arm with regard to leaving the study early (1 RCT, N=202, RR 1.76, 95% CI, 0.86 to 3.63).
				The mean end point of quality of life score was not included in the analysis, as the data were highly skewed.
				Atypical antipsychotics compared to typical antipsychotics (only short term) Five studies compared atypical antipsychotic medications with typical antipsychotic medications.
				In one, the mean end point CGAS score clearly favored young people treated with clozapine (1 RCT, N=21, RR 17.00, 95% CI, 7.74 to 26.26) compared with haloperidol. However, the two groups did not differ in terms of the number of participants showing no improvement (1 RCT, N=21, RR 3.30, 95% CI, 0.41 to 26.81). Another study did not show significant improvement in the mean end point of CGI-I scores for adolescents treated with risperidone as compared with haloperidol (1 RCT, N=34, MD -0.60, 95% CI, -1.45 to 0.25) or for those treated with olanzapine as compared with haloperidol (1 RCT, N= 31, MD -0.70, 95% CI, -1.55 to 0.15).
				Mean end point BPRS score was reported by five studies included in the

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				analysis. No significant difference in the mean end point BPRS score was noted between atypical antipsychotic medications and typical antipsychotic medications (5 RCTs, N=236, MD -1.08, 95% CI, -3.08 to 0.93). Mean end point total PANSS score calculated from the figures reported by one trial showed significant improvement with olanzapine (1 RCT, N=75, MD 27.00, 95% CI, 15.27 to 38.73) and risperidone (1 RCT, N=81, MD 32.90, 95% CI, 19.70 to 46.10) as compared with molindone. Although a different trial reported mean end point SANS and SAPS scores, the data were highly skewed and have not been included in the current analysis.
				No significant difference between atypical and typical antipsychotic medications was reported in two studies for extrapyramidal side effects such as tremors (2 RCTs, N=100, RR 0.46, 95% CI, 0.21 to 1.04) and restlessness (2 RCTs, N=100, RR 0.71, 95% CI, 0.24 to 2.10). One study reported that participants receiving clozapine were three times more likely to have drowsiness on treatment as compared with those given haloperidol (1 RCT, N=21, RR 3.30, 95% CI, 1.23 to 8.85, NNTH 2, 95% CI, 2 to 17). Although not reaching statistical significance, 50% of the participants (5 of 10 participants) receiving clozapine in the study had a drop in absolute neutrophil count to below 1500 per mm ³ . None of the participants in the haloperidol group experienced this adverse effect (1 RCT, N= 21, RR 12, 95% CI, 0.75 to 192.86). For the same study, 2 of 10 participants taking clozapine had seizures. This is clinically significant, although the risk ratio for seizures while taking clozapine as compared with haloperidol was not statistically significant (1 RCT, N= 21, RR 5.45, 95% CI, 0.29 to 101.55).
				The mean end point body weight was not greater for adolescents treated with risperidone (1 RCT, N= 81, MD 0.60, 95% CI, -8.31 to 9.51) or olanzapine (1 RCT, N= 75, MD 2.90, 95% CI, -6.30 to 12.10) as compared with molindone. In this study, mean serum cholesterol concentration showed a statistically significant increase at the end of the treatment period (1 RCT, N=75, MD 25.60, 95% CI, 5.84 to 45.36) for adolescents treated with olanzapine as compared with those given

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				molindone. The serum cholesterol concentration was not increased at the end of the study for adolescents treated with risperidone (1 RCT, N= 75, MD -1.50, 95% CI, -21.01 to 18.01). The mean end point serum prolactin concentration for all three groups (risperidone, olanzapine and molindone) in one study was much higher than the normal reference range, but no difference was reported for the mean end point serum prolactin concentration as compared with molindone for the group of adolescents receiving atypical antipsychotic medications. Although it did not reach statistical significance, 3 of the 10 young people treated with clozapine left the one as the result of adverse effects, of which two were due to a drop in neutrophil count (1 RCT, N=21, RR 3.30, 95% CI, 0.41 to 26.81). When all studies that reported reasons for leaving the study early were taken together, fewer adolescents receiving atypical antipsychotic medications left the study because of adverse effects (3 RCTs, N=187, RR 0.65, 95% CI, 0.36 to 1.15) or for any reason (3 RCTs, N=187, RR 0.62, 95% CI, 0.39 to 0.97).
				Atypical compared to atypical antipsychotic medication (only short term) The numbers of participants with no improvement in CGI score were similar for the groups receiving risperidone and olanzapine (2 RCTs, N=111. RR 1.04, 95% CI, 0.70 to 1.54). In another study, which compared quetiapine and risperidone, no significant difference was reported in the numbers of participants showing no improvement in CGI score (1 RCT, N=22, RR 1.20, 95% CI, 0.52 to 2.79). The mean end point CAGS score was not significantly different (1 RCT, N= 39, MD 4.10, 95% CI, -6.71 to 14.91) for participants receiving clozapine and those taking olanzapine in a different study. However, the mean end point CGI-I score was significantly better for the group of adolescents receiving clozapine as compared with those given olanzapine (1 RCT, N= 39, MD -1.07, 95% CI -1.9 to -0.22). The mean end point BPRS score was not different in two studies that compared risperidone and olanzapine, which are not included in the analysis as the data were skewed. Similarly, another study reported that

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				similar numbers of participants in the groups receiving risperidone or quetiapine showed no response, as defined by less than 40% reduction in baseline PANSS score (1 RCT, N=19, RR 0.48, 95% CI, 0.17 to1.31). When risperidone and quetiapine were compared in a study, no difference between the groups was noted regarding the number of participants who did not improve (1 RCT, N=29, RR 0.33, 95% CI 0.06 to 1.73). In a study which compared risperidone with quetiapine, similar numbers of participants in both groups did not show response on the PANSS score at the end of the study (1 RCT, N=22, RR 1.67, 95% CI 0.52 to 5.33). A study reported a similar mean end point score on BPRS for participants receiving clozapine and olanzapine (1 RCT, N=39, MD - 2.9, 95% CI, -10.13 to 4.33). However, categorical analysis of the data provided on the number of people who did not respond (defined as less than 30% reduction in BPRS score) showed that results favored clozapine over olanzapine (1 RCT, N=39, RR 0.14, 95% CI, 0.03 to 0.60).
				Not much difference was observed in some of the studies included in this review between medications used in the two arms of each trial (various atypical antipsychotics) regarding the mean end point body weight. Data reported by one study showed that the mean end point body weight was similar for adolescents treated with risperidone and those given olanzapine (1 RCT, N=76, MD -2.30, 95% CI, -9.97 to 5.37). However, the mean change in body weight showed that those treated with olanzapine had on average gained 6.1 + 3.6 kg by the end of treatment as compared with an average gain of 3.6 + 4 kg for those treated with risperidone. The mean change in body weight was statistically significant in this study. No significant difference in the number of people who gained ≥ 7% of baseline body weight between groups of adolescents treated with olanzapine and clozapine (1 RCT, N=39, RR 1.75, 95% CI, 0.33 to 9.34).
				In one study, olanzapine had higher mean end point serum cholesterol concentration as compared with those taking risperidone (1 RCT, N= 76, MD -27.10, 95% CI, -50.13 to -4.07). The serum cholesterol concentration

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				for participants treated with olanzapine showed an average increase of 19.9 + 23.9 mg/dL at the conclusion of the study as compared with an average decrease of 10.2 + 26.7 mg/dL for those taking risperidone. The serum prolactin concentration was increased much beyond the normal range by the end of the study for both groups of adolescents treated with atypical antipsychotic medications. However, no significant difference was noted between those who received risperidone and those
				who took olanzapine (1 RCT, N=76, MD -2.30, 95% CI, -9.97 to 5.37). Another study reported that a significantly greater number (10 of 11) of adolescents receiving risperidone as compared with quetiapine had raised serum prolactin concentration (1 RCT, N= 14, RR 4.44, 95% CI, 0.60 to 32.77).
				No difference in the number of participants reporting muscle stiffness or akathisia was noted between adolescents who received olanzapine and those who were given risperidone (1 RCT, N= 19, RR 2.22, 95% CI, 0.53 to 9.37) or quetiapine and risperidone (1 RCT, N= 19, RR 4.44, 95% CI, 0.60 to 32.77). In another study, no significant difference was reported between groups receiving risperidone versus quetiapine regarding their scores on the Barnes Akathisia Scale, the Simpson Angus Akathisia Scale and the Abnormal Involuntary Movement Scale.
				In one study, 11 of a total of 39 participants recruited left the study early. Of these 11 participants, six treated with olanzapine and one treated with clozapine left the study because of non-response, two left the clozapine arm of the trial because of weight gain and one left the olanzapine arm as a result of neutropenia.
				No difference in the number of people leaving the trial early because of side effects was reported for those treated with risperidone or olanzapine (3 RCTs, N=130, RR 1.21, 95% CI, 0.51 to 2.87). Two of 10 adolescents who were treated with quetiapine left the study because of non-response. In total, one of 10 young people from the risperidone group, four of 10 from the quetiapine group and four of 10 from the olanzapine group left

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				the study. In total, only one young person from the olanzapine group left the study because of weight gain.
Bipolar Disorder				
McIntyre et al ⁵⁹ Asenapine 5 mg to 10 mg twice daily vs olanzapine 15 mg on day 1, followed by 5 mg to 20 mg once daily vs placebo	DB, PC, RCT Adult patients, 18 years of age or older, diagnosed with bipolar I disorder, experiencing manic or mixed episodes	N=488 3 weeks (after 1 week placebo run-in period)	Primary: Change in YMRS total score from baseline Secondary: Change from baseline in Clinical Global Impression for Bipolar Disorder (CGI-BP), MADRS, percentage of responders (≥50% reduction in YMRS total score), percentage of remitters (YMRS total score ≤12 at endpoint), adverse events	Primary: Asenapine was associated with a statistically significant reduction in YMRS total score from baseline, compared to placebo (-10.8 vs -5.5; P<0.0001). Statistically significant benefit with asenapine over placebo was noted as early as day-2 of therapy. Olanzapine was associated with a statistically significant reduction in YMRS total score from baseline, compared to placebo (-12.6 vs -5.5; P<0.0001). Secondary: Asenapine was associated with a statistically significant reduction in CGI-BP score from baseline, compared to placebo (-1.2 vs -0.7; P<0.01). Olanzapine was associated with a statistically significant reduction in CGI-BP score from baseline, compared to placebo (-1.4 vs -0.7; P<0.001). Asenapine was not associated with significant difference in MADRS reduction at endpoint compared to placebo (-3.2 vs -1.8; P>0.05). Olanzapine was associated with a statistically significant reduction in MADRS score from baseline, compared to placebo (-4.2 vs -1.8; P<0.01). Significantly greater percentage of patients in the asenapine group experienced a response (42.3%) or remission (40.2%) compared to patients receiving placebo (25.2% and 22.3%, respectively; P<0.01 for both). The NNT values for YMRS response and remission were 6. Significantly greater percentage of patients in the olanzapine group experienced a response (50%) or remission (39.4%) compared to patients receiving placebo (25.2% and 22.3%, respectively; P<0.005 for

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				both). The NNT values for YMRS response and remission were 5 and 6, respectively.
				Treatment-related adverse events were reported by 60.8%, 52.9%, and 36.2% of asenapine-, olanzapine-, and placebo-treated patients.
				Most common adverse events with asenapine that occurred at more than twice the frequency of placebo included sedation (18.6 vs 4.8%), dizziness (11.9 vs 3.8%), somnolence (8.8 vs 1.9%), fatigue (6.2 vs 1.9%, and oral hypoasthenia (5.2 vs 1%).
				Most common adverse events with olanzapine that occurred at more than twice the frequency of placebo included sedation (18.5%), dry mouth (14.3 vs 1%), dizziness (8.5%), somnolence (7.4%), and increased weight (6.9 vs 1%).
				The incidence of EPS events was 7.2% with asenapine, 7.9% with olanzapine and 2.9% with placebo.
				Asenapine, olanzapine, and placebo groups experienced the following weight gain: 1.6 kg, 1.9 kg, and 0.3 kg, respectively. NNH values vs placebo for the incidence of clinically significant weight gain were 17 and 8 in patients who received asenapine and olanzapine, respectively.
McIntyre et al ⁶⁰	DB, MC, PC, RCT	N=480	Primary:	Primary:

placebo			total score), percentage of remitters (YMRS total score <12 at endpoint), adverse events	BP score from baseline, compared to placebo (-1.2 vs -0.8; P<0.05). Olanzapine was associated with a statistically significant reduction in CGI-BP score from baseline, compared to placebo (-1.5 vs -0.8; P<0.0001). Asenapine was not associated with a significant difference in MADRS reduction at endpoint compared to placebo (-3.0 vs -1.9; P>0.05). Olanzapine was associated with a statistically significant reduction in MADRS score from baseline, compared to placebo (-4.1 vs -1.9; P<0.01). The response (42.6 vs 34%) and remission (35.5 vs 30.9%) rates did not significantly differ between asenapine and placebo groups (P>0.05). Significantly greater percentage of patients in the olanzapine group experienced a response (54.7%) or remission (46.3%) compared to patients receiving placebo (34% and 30.9%, respectively; P<0.05 for both). The NNT values for YMRS response and remission were 5 and 7, respectively. Treatment-related adverse events were reported by 55.1%, 46.8%, and 27.6% of asenapine-, olanzapine-, and placebo-treated patients. Most common adverse events with asenapine that occurred at more than twice the frequency of placebo included sedation (8.6 vs 3.1%), dizziness (10.3 vs 2.0%), somnolence (11.9 vs 3.1%), weight gain (6.5 vs 0.0%, and vomiting (5.4 vs 2%). Most common adverse events with olanzapine that occurred at more than twice the frequency of placebo included sedation (14.1%), dizziness (6.3%), somnolence (11.2%), increased appetite (6.3 vs 1%) and increased weight (9.3%).
				The incidence of EPS events was 10.3% with asenapine, 6.8% with

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
Szegediet al ⁶¹ Asenapine 5 mg to 10 mg twice daily vs olanzapine 15 mg once daily on day 1, followed by 5 mg to 20 mg once daily vs placebo	MA, PH of 2 studies by McIntyre et al Adult patients, 18 years of age or older, diagnosed with bipolar I disorder, experiencing depressive symptoms, with YMRS total score >20 or CGI-BP-D score >4, or mixed symptoms	N=977 3 weeks (after 1 week placebo run-in period)	Primary: Change in MADRS, CGI-BP-D, and PANSS Marder anxiety/depression factor scores from baseline Secondary: Not reported	Asenapine, olanzapine, and placebo groups experienced the following weight gain: 0.9 kg, 2.6 kg, and 0.1 kg, respectively. NNH values vs placebo for the incidence of clinically significant weight gain were 19 and 7 in patients who received asenapine and olanzapine, respectively. Primary: In patients with baseline MADRS scores ≥20, CGI-BP-D scores ≥4, or those experiencing a mixed episode, there was no statistically significant difference between asenapine and olanzapine (P>0.05) in terms of improvement in MADRS scores from baseline on day-21; though, asenapine was more effective than placebo (P<0.05). In patients with baseline MADRS scores ≥20, significantly more patients in the asenapine group experienced remission compared to placebo on day-21 (70 vs 33%; P=0.012); though, asenapine was not associated with a significantly greater remission rate compared to olanzapine (70 vs 48%; P=0.066). In patients with baseline CGI-BP-D severity scores ≥4 or those exhibiting a mixed episode more patients in the asenapine group experienced remission compared to placebo on day-21 (P≤0.05). In these patients, olanzapine was associated with significantly greater remission rate compared to placebo on day-21 (P<0.05). In patients with MADRS scores ≥20, CGI-BP-D severity scores ≥4 or those exhibiting a mixed episode at baseline, there was no statistically significant difference between asenapine and olanzapine in terms of CGI-BP-D score reduction from baseline on day-21 (P>0.05). In patients with either CGI-BP-D severity scores ≥4 or those exhibiting a mixed episode at baseline, there was no statistically significant difference between asenapine and olanzapine in terms of PANSS Marder anxiety/depression factor score reduction from baseline on day-21 (P>0.05). Patients with baseline MADRS scores >20 who received

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
McIntyre et al ⁶² Continuing asenapine 5 mg to 10 mg twice daily	DB, ES Adult patients, 18 years of age or	N=480 9 weeks	Primary: Change in YMRS scores from baseline	asenapine exhibited a statistically greater improvement in PANSS Marder anxiety/depression scores compared to olanzapine on day-7 (P=0.001). Secondary: Not reported Primary: At day-84, there was no statistically significant difference between asenapine and olanzapine in the YMRS score reduction from baseline (-24.4 vs -23.9; P value not reported).
vs continuing olanzapine 5 mg to 20 mg once daily vs	older, diagnosed with bipolar I disorder, experiencing manic or mixed episodes, with YMRS total score >20		Secondary: YMRS response and remission rates, CGI-BP, PANSS, MADRS, adverse events	Secondary: At day-84, there were no statistically significant differences between asenapine and olanzapine in terms of YMRS response (77 vs 82%) and remission rates (75 vs 79%; P>0.05 for both). The relative NNT values for olanzapine relative to asenapine in terms of YMRS response and remission were 40 and 48.
switching from placebo to asenapine in a blinded fashion				At day-84, there was no statistically significant difference between asenapine and olanzapine in the CGI-BP score reduction from baseline (P>0.05). At day-84, there were no statistically significant differences between asenapine and olanzapine in either the PANSS total score or MADRS score reduction from baseline (P>0.05). There were no marked differences in the incidence of treatment-emergent or treatment-related adverse events between asenapine and olanzapine groups (P value not reported). The most frequently reported adverse events were sedation, dizziness, and insomnia with asenapine and sedation, headache, somnolence and weight gain with olanzapine. The incidence of EPS adverse events was 10% with placebo/asenapine, 15% with asenapine and 13% with olanzapine. Mean weight gain after 12 weeks of therapy was 0.5 kg with placebo/asenapine, 1.9 kg with asenapine, and 4.1 kg with olanzapine.

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				The percentage of patients with clinically significant weight gain was greater with olanzapine (31%) than with asenapine (19%) after 12 weeks of therapy. The estimated NNH for clinically significant weight gain for olanzapine relative to asenapine was 9.
Continuing asenapine 5 mg to 10 mg twice daily vs continuing olanzapine 5 mg to 20 mg once daily vs switching from placebo to asenapine in a blinded fashion	DB, DD, MC, PG, ES of the 2 studies by McIntyre et al Adult patients, 18 years of age or older, diagnosed with bipolar I disorder, experiencing manic or mixed episodes, with YMRS total score ≥20	N=218 40 weeks (in addition to the 3 week RCT and 12 week prior ES)	Primary: Adverse events Secondary: YMRS response at 52 weeks, YMRS remission at 52 weeks, change in YMRS scores, CGI- BP scores, and MADRS scores	Primary: The incidence of treatment-emergent adverse events was 71.9%, 86.1%, and 79.4% with placebo/asenapine, asenapine, and olanzapine, respectively. The most frequent treatment-emergent adverse events were headache and somnolence with placebo/asenapine, insomnia, sedation and depression with asenapine, and weight gain, somnolence and sedation with olanzapine. Prolactin levels >4 times the upper limit of normal occurred in 0%, 6.5%, and 2.9% of patients receiving placebo/asenapine, asenapine and olanzapine, respectively. Shifts from normal to high fasting glucose levels occurred in 10%, 26%, and 22.2% of patients receiving placebo/asenapine, asenapine and olanzapine, respectively. The NNH value for asenapine relative to olanzapine was 27. Clinically significant weight gain occurred in 21.9%, 39.2%, and 55.1% of patients receiving placebo/asenapine, asenapine and olanzapine, respectively. The NNH value for olanzapine relative to asenapine was 7. Secondary: At week-52, there was no statistically significant difference between asenapine and olanzapine in the YMRS score reduction from baseline (-28.6 vs -28.2; P value not reported). At week-52, there was no statistically significant difference between asenapine and olanzapine in terms of YMRS remission and response rates (97.8 vs 98.4%; P value not reported).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
Calabrese et al ⁶⁴ Quetiapine 300 mg/day vs quetiapine 600 mg/day vs placebo			Primary: Mean change in MADRS total score from baseline to week 8 Secondary: Changes in CGI-I, CGI-S and HAM-D scores from baseline to week 8, rates of and time to response (≥50% improvement in the total MADRS score	At week-52, there was no statistically significant difference between asenapine and olanzapine in the CGI-BP mania severity score reduction from baseline (-3.5 vs -3.2; P value not reported). At week-52, there was no statistically significant difference between asenapine and olanzapine in the MADRS score reduction from baseline (-4.8 vs -4.4; P value not reported). Primary: Quetiapine at either dose demonstrated statistically significant improvement in MADRS total scores compared to placebo from week 1 onward (P<0.001 for all assessments). Secondary: Quetiapine-treated patients experienced a statistically significant improvement (P<0.001) on the CGI-S as early as week 1 that was sustained till the end of the study for both doses; a larger percentage of patients improved on the CGI-I scale in the 600 mg/day (55.9%) and 300 mg/day (64.0%) quetiapine groups compared to the placebo group (34.3%) at the final assessment. The mean change from baseline in the HAM-D scores at week 8 was -13.84, -13.38, and -8.54 in the quetiapine 600 mg/day, quetiapine 300
			from baseline) and remission (MADRS total score ≤12)	mg/day, and placebo groups respectively (P<0.001 for both quetiapine doses vs placebo). The proportions of patients meeting response criteria at the final assessment were 58.2% in the quetiapine 600 mg/day group, 57.6% in the quetiapine 300 mg/day group, and 36.1% in the placebo group. The proportion of patients meeting remission criteria were 52.9% in the quetiapine 600 mg/day and 300 mg/day groups, and 28.4% in the placebo group. Treatment-emergent mania rates were low and similar for the quetiapine

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				and placebo groups (3.2% and 3.9%, respectively).
Tohen et al ⁶⁵	DB, MC, PC, PG, RCT	N=833	Primary: Change in MADRS	Primary: During all eight study weeks, the olanzapine and olanzapine-fluoxetine
Olanzapine 5-20 mg/day	Patients 18 years	8 weeks	total score from baseline to week 8	groups showed statistically significant improvement in depressive symptoms compared to the placebo group (olanzapine, -15.0; P=0.002;
vs	or older diagnosed with bipolar I		Secondary:	olanzapine-fluoxetine, -18.5; P<0.001). The olanzapine-fluoxetine group showed statistically greater improvement than the olanzapine group at
olanzapine-fluoxetine 6/25 mg	disorder, depressed		Changes in CGI- BP, YMRS and	week 8 (P=0.01).
vs	шор. сосси		HAM-A scores from baseline to week 8,	Secondary: The olanzapine group showed greater mean improvement on the CGI-BP
			rates of and time to	than the placebo group (P=0.004), and the olanzapine-fluoxetine group
olanzapine-fluoxetine 6/50 mg			response (≥50% improvement in the total MADRS score	showed greater mean improvement than both the placebo (P<0.001) and olanzapine (P=0.16) groups.
vs			from baseline) and remission (MADRS	Treatment-emergent mania (YMRS total score <15 at baseline and ≥15 subsequently) did not differ among groups (placebo, 6.7%; olanzapine,
olanzapine-fluoxetine 12/50 mg			total score ≤12 at an end point and	5.7%; olanzapine-fluoxetine, 6.4%).
vs			completion of ≥4 weeks of study)	Remission criteria were met by 24.5% (87/355) of the placebo group, 32.8% (115/351) of the olanzapine group, and 48.8% (40/82) of the olanzapine-fluoxetine group.
placebo				Adverse events for the olanzapine-fluoxetine group were similar to those in the olanzapine group, but also included higher rates of nausea and diarrhea.

Vatham et al ⁶⁷	MC OL PRO RCT	N=40	in depression by HAM-D-21 and MADRS scales, safety (assessed by the evaluation of treatment-emergent adverse events, discontinuations due to adverse events, vital sign measurements, and clinical laboratory tests)	scores (all P>0.05). With a response definition of ≥50% reduction in the YMRS score at endpoint, 62.1% of olanzapine-treated patients responded compared to 59.5% of the risperidone-treated patients. Olanzapine-treated patients experienced greater elevations in liver function enzymes (P<0.05) and increase in weight (2.5 kg vs 1.6 kg; P=0.004); risperidone-treated patients were more likely to experience prolactin elevation (51.73 ng/mL vs 8.23 ng/mL; P<0.001) and sexual dysfunction (total score increase of 1.75 vs 0.64; P=0.049).
Yatham et al ⁶⁷ Continuation of usual oral atypical antipsychotic (olanzapine, quetiapine, or risperidone) vs switching to long-acting risperidone 25 mg injection every 2 weeks	MC, OL, PRO, RCT Stable adults aged 18-65 years of age diagnosed with Bipolar I or Bipolar II according to DSM-IV criteria and currently on one oral atypical antipsychotic agent in combination with a maximum of two of lithium, valproate or lamotrigine; and, if applicable, one antidepressant	N=49 6 months	Primary: Safety measures (adverse events, lab tests, vital signs, weight and movement disorders scales such as the BARS, SAS, and AIMS) and efficacy measures (CGI-S, YMRS, MADRS, HAM-A, EuroQol EQ-5D, VAS and time to intervention) Secondary: Not reported	Primary: At least one treatment emergent adverse event was reported by 16 (70%) of patients in the injection group and 19 (73%) in the oral group (P value not reported). There were no clinical significant changes in laboratory tests in either group (P value not reported). There were no significant changes in weight or heart rate within each group; however, diastolic blood pressure was significantly different at the study endpoint in the risperidone injection group (–5.2±11.0; P=0.033). There were significant between group differences in reduction of diastolic blood pressure favoring the injection group (P<0.05). There were no significant differences between groups for mean changes in AIMS (P=0.95), SAS (P=0.11) or BARS (P=0.52) scores. The differences in changes in CGI-S and YMRS scores between the two groups was not significant (P=0.67 and P=0.31, respectively). There were also no significant differences in changes in MADRS or HAM-A scores between the groups (P values not reported).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
Cipriani et al ⁶⁸ Atypical antipsychotics	MA Patients, 18 years	N=16,073 3 weeks	Primary: Mean change in YMRS scores and	There were no significant differences between the groups on changes in VAS, EuroQuol EQ-5D, or scores on the resource use questionnaire (P vales not reported). There were no significant differences between groups on the number of interventions or time to intervention (P value not reported). Secondary: Not reported Primary: Haloperidol (SMD, -0.56; 95%CI, -0.69 to -0.43), risperidone (-0.50; -0.63 to -0.38), olanzapine (-0.43; -0.54 to -0.32), lithium (-0.37; -0.63 to -0.11),
(aripiprazole, asenapine, olanzapine, paliperidone, quetiapine, risperidone, ziprasidone)	of age or older, with a diagnosis of bipolar disorder (manic or mixed episode)		dropout rates Secondary: Responder rate	quetiapine (-0.37; -0.51 to -0.23), aripiprazole (-0.37; -0.51 to -0.23), carbamazepine (-0.36; -0.60 to -0.11, asenapine (-0.30; -0.53 to -0.07), valproate (-0.20; -0.37 to -0.04), and ziprasidone (-0.20; -0.37 to -0.03) were significantly more effective than placebo in terms of mean change in YMRS scores from baseline.
anticonvulsants (carbamazepine, valproate, gabapentin, lamotrigine,				Gabapentin, lamotrigine, and topiramate were not significantly different from placebo in the mean change in YMRS scores from baseline (P value not reported).
topiramate) vs				Risperidone was not significantly different from either olanzapine or quetiapine in the mean change in YMRS scores from baseline (P value not reported).
haloperidol vs				Haloperidol had the highest number of significant differences and was significantly more effective than lithium (SMD, -0.19; 95% CI -0.36 to -0.01), quetiapine (-0.19; -0.37 to 0.01), aripiprazole (-0.19; -0.36 to -0.02),
lithium vs				carbamazepine (-0.20; -0.36 to -0.01), asenapine (-0.26; -0.52 to 0.01), valproate (-0.36; -0.56 to -0.15), ziprasidone (-0.36; -0.56 to -0.15), lamotrigine (-0.48; -0.77 to -0.19), topiramate (-0.63; -0.84 to -0.43), and gabapentin (-0.88; -1.40 to -0.36).
placebo				Risperidone and olanzapine exhibited a similar profile of comparative

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				efficacy to haloperidol, being more effective than valproate, ziprasidone, lamotrigine, topiramate, and gabapentin. Topiramate and gabapentin were significantly less effective compared to all other antimanic drugs. Olanzapine was associated with significantly greater improvement in YMRS scores from baseline compared to asenapine (22; -0.37 to -0.08).
				Olanzapine, risperidone, and quetiapine were associated with significantly lower dropout rate compared to lithium, lamotrigine, placebo, topiramate, and gabapentin (P value not reported). Aripiprazole was not statistically different from olanzapine, risperidone, and quetiapine in terms of the likelihood of discontinuing therapy (P value not reported).
				When the evaluated antimanic drugs were ordered by their probability to be the best treatment in terms of both efficacy (improvement on the YMRS) and tolerability (assessed via dropout rates), risperidone was found to be the most effective treatment option. In order of decreased efficacy, the next best treatment options were olanzapine, haloperidol, quetiapine, carbamazepine, aripiprazole, valproate, lithium, ziprasidone and asenapine. Lamotrigine, topiramate and gabapentin were found to be less effective than placebo.
				Secondary: Compared to placebo, aripiprazole (Odds Ratio [OR], 0.50; 0.38 to 0.66), asenapine (0.49; 0.29 to 0.83), carbamazepine (0.40; 0.22 to 0.77), valproate (0.50; 0.36 to 0.70), haloperidol (0.44; 0.33 to 0.58), lithium (0.55; 0.38 to 0.79), olanzapine (0.46; 0.36 to 0.58), quetiapine (0.50; 0.37 to 0.66), and risperidone (0.47; 0.35 to 0.61) were associated with better response rates.
				The difference in response rates between olanzapine and asenapine, olanzapine and risperidone, as well as quetiapine and risperidone were not statistically significant.

				significant compared to placebo (-0.35 ; 95% CI, -0.49 to -0.22). The test for overall effect was Z=5.07; P<0.00001. No significant heterogeneity was detected in the SMD between these studies (Chi ² =3.42, df=7, P=0.84, I ² =0%).
				The test for overall effect of atypical antipsychotics in combination with mood stabilizers compared to placebo + mood stabilizers was also statistically significant (-0.55 ; 95% CI, -0.75 to -0.34). The test for overall effect was Z=5.22; P<0.00001. There was no heterogeneity in the SMD between these studies (Chi²=1.85, df=2, P=0.40, I²=0%).
				In order to ascertain if atypical antipsychotics have similar efficacy in treating manic symptoms in mixed episodes as in pure mania, the SMD for atypical antipsychotics was calculated separately for these two conditions. For this analysis, effect sizes of seven of the nine included RCTs that reported data for pure manic and mixed episodes separately were evaluated. The SMD for atypical antipsychotics compared to placebo was comparable in both pure mania (-0.56; 95% CI, -0.69 to -0.42; N=1522) and mixed episodes (-0.44; 95% CI, -0.59 to -0.29; N=727). Further, no significant differences were noted in the mean YMRS change scores for atypical antipsychotics between manic and mixed patients in each study (-0.00; 95% CI, -0.12 to 0.12; Z=0.02, P=0.99). The SMD of mean change in depression scores in two trials was statistically significant in favor of the atypical antipsychotics group
				compared to placebo (-0.30 ; 95% CI, -0.47 to -0.13). Test for overall effect was highly statistically significant (Z=3.48, P<0.001). There was no significant heterogeneity in the SMDs between the two studies (Chi ² =0.61, df=2, P=0.74, I ² =0%).
Loebel et al ²⁸⁵ Each patient received therapeutic level of lithium or valproate.	DB, MC, PC, RCT Outpatients 18 to 75 years of age with a diagnosis of bipolar I disorder	N=348 6 weeks	Primary: Change in MADRS from baseline to week 6 Secondary:	Primary: The least squares mean change from baseline to week 6 in MADRS total score was significantly greater for the lurasidone group compared with the placebo group (-17.1 versus -13.5; P=0.005 [effect size=0.34]). This was staltically improved compared to placebo starting week three, and was maintained at all subsequent study visits (weekly until week 6;

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
vs placebo once daily	who were experiencing a major depressive episode, with or without rapid cycling, without psychotic features, and with a history of at least one lifetime bipolar manic or mixed manic episode		Change in CGI-BP, 16-item Quick Inventory of Depressive Symptomatology self-rated version, HAM-A, Sheehan Disability Scale, and Quality of Life Enjoyment and Satisfaction Questionnaire— Short Form from baseline to week 6	P<0.001, P<0.001, P<0.05, P<0.01 for weeks 3, 4, 5 and six respectively). Secondary: Least squares mean change from baseline to week 6 in the CGI-BP depression severity score was significantly greater for the lurasidone group compared with the placebo group (-1.96 versus -1.51; P=0.003 [effect size=0.36]). This was stattically improved compared to placebo starting week two, and was maintained at all subsequent study visits (weekly until week 6; P<0.05, P<0.001, P<0.001, P<0.001, P<0.001, P<0.01 for weeks 2, 3, 4, 5 and six respectively). There was a statistically significant reduction from baseline to week 6 in core depressive symptoms (MADRS-6 subscale score) in the lurasidone group compared with the placebo group (-11.6 versus -9.1; P=0.003). Treatment with lurasidone was associated with greater endpoint improvement compared with placebo on each of the 10 MADRS items, with a significant difference achieved on the following items: apparent sadness, reported sadness, reduced sleep, lassitude, inability to feel, and pessimistic thoughts (P-values varied all <0.05). A significantly greater proportion of patients met a priori response criteria after 6 weeks of treatment with lurasidone compared with placebo (57% versus 42%; P=0.008 [number needed to treat=7]). Median time to response was significantly shorter for the lurasidone group compared with placebo (28 versus 42 days; log-rank P<0.001). The proportion of patients achieving remission at endpoint was significantly greater in the lurasidone group compared with placebo (50% versus 35%; P=0.008 [number needed to treat=7]). The median time to remission was significantly shorter for the lurasidone group compared with placebo (35 versus 43 days, P=0.001). No significant treatment interactions by gender, race, ethnicity, or age were observed for either the MADRS total score or the CGI-BP

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				depression severity score. Least squares mean changes in scores from baseline to endpoint (lurasidone versus placebo) for secondary efficacy assessments were as follows: the Quick Inventory of Depressive Symptomatology (-8.1 versus -5.9; P<0.001); the Hamilton anxiety scale (-8.0 versus -6.0; P=0.003); the Quality of Life, Enjoyment, and Satisfaction Questionnaire—Short Form (+22.2 versus +15.9; P=0.003); and the Sheehan Disability Scale (-9.5 versus-7.0; P=0.012). The incidence of extrapyramidal symptom-related adverse events was 15.3% in the lurasidone group and 9.8% in the placebo group; 11% of the lurasidone group and 4% of the placebo group received treatment with anticholinergic medication for acute extrapyramidal symptoms. Treatment with adjunctive lurasidone was associated with a small but significantly greater endpoint change compared with placebo in the Barnes Akathisia Rating Scale score global score (0.1 versus 0.0; P=0.009), and the Simpson-Angus Scale score (0.03 versus 0.01; P=0.018), but no difference for the Abnormal Involuntary Movement Scale total score (both groups, 0.0).
Loebel et al ²⁸⁶ Lurasidone 20 to 60 mg/day Or	DB, MC, PC, PG, RCT Outpatients 18 to 75 years of age with a diagnosis of	N=485 6 weeks	Primary: Mean change in MADRS total score from baseline to week 6	Primary: The least squares mean change from baseline to week 6 in MADRS total score was significantly greater than seen with placebo (-10.7) for the lurasidone 20 to 60 mg group (-15.4; P<0.001 [effect size=0.51]) and the lurasidone 80 to 120 mg group (-15.4; P<0.001 [effect size=0.51]). For both dosages this was staltically improved compared to placebo starting
lurasidone 80 to 120 mg/day	bipolar I disorder who were experiencing a		Secondary: Change in CGI-BP, 16-item Quick	week two, and was maintained at all subsequent study visits (weekly until week 6; P<0.05 for all).
placebo	major depressive episode, with or without rapid cycling, without psychotic features, and with a history of at least one		Inventory of Depressive Symptomatology self-rated version, HAM-A, Sheehan Disability Scale, and Quality of Life	Secondary: The least squares mean change from baseline to week 6 in CGI-BP depression severity score was significantly greater than seen with placebo (-1.1) for the lurasidone 20 to 60 mg group (-1.8; P<0.001 [effect size=0.61]) and the lurasidone 80 120 mg group (-1.7; P<0.001 [effect size=0.50]). For the lurasidone 20 to 60 mg group and the 80 to

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
	lifetime bipolar manic or mixed manic episode		Enjoyment and Satisfaction Questionnaire— Short Form from baseline to week 6	120 mg group, this was staltically improved compared to placebo starting weeks two and one respectively, and was maintained at all subsequent study visits (weekly until week 6; P<0.05 for all). There was a statistically significant reduction from baseline to week 6 in core depressive symptoms (MADRS-6 subscale score) for the lurasidone 20 to 60 mg group (-10.4; P<0.001) and the lurasidone 80 to 120 mg group (-10.4; P<0.001) relative to the placebo group (-6.9). Lurasidone was associated with significantly greater improvement than placebo on seven of the 10 MADRS items in both the 20 to 60 mg and 80 to 120 mg groups. A significantly greater proportion of subjects met a priori response criteria after 6 weeks of treatment with lurasidone 20 60 mg (53%; P<0.001 [number needed to treat=5]) and lurasidone 80 to 120 mg (51%; P<0.001 [number needed to treat=5]) compared with placebo (30%). Median time to response was shorter in the lurasidone 20 to 60 mg group (34 days) and the 80 to 120 mg group (30 days) compared with the placebo group (42 days; log-rank P<0.01 for both comparisons). The proportion of subjects achieving remission at endpoint was significantly greater in the lurasidone 20 to 60 mg group (42%; P=0.001 [number needed to treat=6]) and the lurasidone 80 to 120 mg group (40%; P=0.004 [number needed to treat=7]) compared with the placebo group (25%). No significant treatment interactions by gender, age, race, or ethnicity were observed for either the MADRS total score or the CGI-BP depression severity score. Treatment with both dosages of lurasidone was associated with significant improvement compared with placebo in anxiety symptoms, as measured by the clinician-rated Hamilton anxiety scale, the patient-rated Quick Inventory of Depressive Symptomatology, the Quality of Life, Enjoyment, and Satisfaction Questionnaire, and the Sheehan Disability

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				Scale. The incidence of extrapyramidal symptom-related adverse events was less than 10% in both lurasidone groups, with a modest dose-related increase in incidence. The proportion of patients who received treatment with anticholinergic medication for acute extrapyramidal symptoms was 3.7% in the lurasidone 20 to 60 mg group, 4.9% in the lurasidone 80 to 120 mg group, and 1.9% in the placebo group. Least squares mean changes from baseline to endpoint (lurasidone 20 to 60 mg and 80 to 120 mg versus placebo) were small for the Barnes Akathisia Scale (0.0 and 0.2 versus -0.1), and for the Simpson Angus Scale (0.02 and 0.02 versus 0.00). There were no significant changes from baseline to endpoint in the Abnormal Involuntary Movement Scale total score in any treatment group with no statistically significant differences between the lurasidone
Treatment-Resistant Depress	ion			treatment groups and the placebo group.

				There was no significant difference in the rate of discontinuation among patients receiving the four antipsychotic agents (P=0.13). Patients experienced only mild side effects with all of the evaluated antipsychotics.
Bauer et al ⁷⁶ Quetiapine XR 150 mg daily, in addition to ongoing antidepressant therapy vs quetiapine XR 300 mg daily, in addition to ongoing antidepressant therapy vs placebo, in addition to ongoing antidepressant therapy	MA Patients, aged 18 to 65 years, diagnosed with MDD based on the DSM-IV criteria, with HAM-D total score ≥20 and a HAM-D Item 1 (depressed mood) score ≥2 after an adequate trial (>6 weeks of therapy at an adequate dose)of one of the following antidepressants: amitriptyline, bupropion, citalopram, duloxetine, escitalopram, fluoxetine, paroxetine, sertraline or venlafaxine	N=939 6 weeks	Primary: Change in MADRS total score at week- 6 Secondary: MADRS response rate, MADRS remission rate, HAM-D, HAM-A, Pittsburgh Sleep Quality Index (PSQI), CGI-S scores, adverse events	Primary: Quetiapine XR 150 mg and 300 mg daily doses were associated with significant improvements in MADRS total scores from baseline, compared to placebo (-14.5 vs -14.8 vs -12.0, respectively; P<0.001 for both). Significant benefit of quetiapine XR over placebo was noted as early as week-1 and was sustained through week-6. Secondary: Quetiapine XR 300 mg daily was associated with significantly greater MADRS response rate compared to placebo (58.3 vs 46.2%; P<0.01). Quetiapine XR 150 mg daily was associated with marginal benefit over placebo in terms of MADRS response rate, but the difference did not reach statistical significance (53.7 vs 46.2%; P=0.063). Quetiapine XR 150 mg and 300 mg daily doses were associated with significantly greater remission rates compared to placebo (35.6 vs 36.5 vs 24.1%, respectively; P<0.01 for both). Both quetiapine XR doses were associated with significant improvement from baseline, compared to placebo, in HAM-D, HAM-A, PSQI and CGI-S scores at week-6 of therapy (P<0.05). Significantly more patients in the quetiapine XR 150 mg and 300 mg groups discontinued the study due to adverse events compared to the placebo group (8.9 vs 15.4 vs 1.9%, respectively). In the quetiapine XR groups, the most common adverse events leading to discontinuation were somnolence and sedation. The incidence of adverse events potentially related to EPS side effects
				was 3.8%, 6.4% and 4.2% of patients in the quetiapine XR 150 mg, 300 mg, and placebo groups.

Komosa et al ⁷⁷ Atypical antipsychotics (aripiprazole, amisulpride*, olanzapine, quetiapine, risperidone) as monotherapy or augmentation therapy to antidepressants vs placebo or antidepressants	SR Patients with unipolar major depressive disorder or dysthymia	N=8,487 28 studies 12 to 52 weeks	Primary: Treatment response (reduction of ≥50% on the HAM-D or the MADRS or at least much improved score on the CGI scale) Secondary: MADRS scores, HAM-D scores, HAM-A scores, remission (HAM-D ≤7 or MADRS ≤10), adverse events	The incidence of suicidality was 1.0%, 0.0% and 0.6% of patients in the quetiapine XR 150 mg, 300 mg, and placebo groups. Mean weight gain from baseline to week-6 in the quetiapine XR 150 mg, 300 mg, and placebo groups were 0.9 kg, 1.3 kg, and 0.2 kg, respectively. Secondary: Not reported Primary: According to efficacy data from three available studies, aripiprazole augmentation therapy was associated with an odds ratio of a positive treatment response of 0.48 (95% CI, 0.37 to 0.63; P value not reported). There was no significant difference between olanzapine augmentation therapy and placebo in treatment response rate (P value not reported). According to efficacy data from three available studies, quetiapine monotherapy was associated with an odds ratio of a positive treatment response of 0.52 (95% CI, 0.41 to 0.66; P value not reported). According to efficacy data from two available studies, quetiapine augmentation therapy was associated with an odds ratio of a positive treatment response of 0.68 (95% CI, 0.52 to 0.90; P value not reported). According to efficacy data from two available studies, risperidone augmentation therapy was associated with an odds ratio of a positive treatment response of 0.57 (95% CI, 0.36 to 0.89; P value not reported). Secondary: According to efficacy data from three available studies, aripiprazole
				augmentation therapy was associated with a reduction in MADRS scores from baseline, compared to placebo (MD, -3.04; 95% CI, -4.09 to -2.00; P

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
Study and Drug Regimen			End Points	value not reported). According to efficacy data from one available study, aripiprazole augmentation therapy was associated with a significant improvement in CGI scores from baseline, compared to placebo (OR, 0.51; 95% CI, 0.34 to 0.78; P value not reported). Compared to placebo, aripiprazole augmentation therapy was also associated with a significantly greater odds ratio of achieving remission (OR, 0.48; 05%CI, 0.36 to 0.64). Olanzapine augmentation therapy was associated with a lower discontinuation rate due to inefficacy compared to placebo. There were no significant differences in efficacy endpoints between the olanzapine monotherapy group and either placebo or antidepressant comparator groups. However, olanzapine augmentation therapy was associated with a significant reduction in MADRS scores from baseline, compared to placebo (MD, -2.84; 95% CI, -5.48 to -0.20; P value not reported). Olanzapine augmentation therapy was likewise associated with a significant improvement from baseline, compared to placebo in anxiety symptoms, as measured by the HAM-A scale (MD, -1.44; 95%CI, -2.81 to -0.06). There was no significant difference between olanzapine augmentation therapy and placebo in HAM-D score reduction from baseline (MD, -7.90; 95%CI, -16.63 to 0.83). According to efficacy data from two available studies, quetiapine augmentation therapy was associated with a significant improvement in CGI scores from baseline, compared to placebo (OR, 0.64; 95% CI, 0.49 to 0.84; P value not reported). Significantly more patients receiving quetiapine augmentation therapy, compared to placebo, experienced remission (OR, 0.52; 95%CI, 0.38 to 0.71). Likewise quetiapine augmentation therapy was associated with a significant improvement
				from baseline, compared to placebo in MADRS scores (OR, 6.80; 95%CI, 0.52 to 0.90) and HAM-A scores (OR, 0.23; 95%CI, 0.08 to 0.70). Significantly more patients receiving risperidone augmentation therapy, compared to placebo, experienced remission (OR, 0.39; 95%CI, 0.22 to 0.69). HAM-D scores were significantly improved from baseline,

Kent et al ²⁸⁷ Risperidone oral solution once daily (<45 kg, 0.125 mg/day; ≥45 kg, 0.175 mg/day) vs Risperidone oral solution once daily (<45 kg, 1.25 mg/day; ≥45 kg, 1.75 mg/day) vs placebo oral solution once daily	DB, MC, OL (phase 2) PC, RCT Patients 5 to 17 years of age with a diagnosis of autistic disorder, weighing at least 20 kg, with a mental age >18 months	N=77 6 week (DB phase) 6 months (OL phase)	Primary: Mean change in the ABC-I at week six Secondary: Mean change in other ABC subscale scores at week 6, change in CGI-S score and CY_BOCS compulsion subscale score at week 6, response rate, and percentage of patients with CGI-I ratings of "much improved" or "very much improved" at	compared to placebo with risperidone augmentation therapy (OR, 0.60; 95%CI, 0.38 to 0.95). There was no significant difference between risperidone and placebo augmentation groups in MADRS scores at endpoint (MD, -1.85; 95%ci, -9.71 to 5.47). Compared to placebo, aripiprazole augmentation therapy was associated with an increased risk of weight gain, akathisia, and EPS. Aripiprazole was not associated with an increased incidence of sedation or tremor. Olanzapine augmentation was associated with an increased risk of sedation and weight gain. Risperidone was associated with an increased risk of weight gain and prolactin release. Risperidone therapy was not associated with an increased risk of EPS events or sedation. Quetiapine was associated with an increased risk of sedation and weight gain. Quetiapine was not associated with an increased risk of sedation and weight gain. Quetiapine was not associated with an increased risk of sedation and weight gain. Quetiapine was not associated with an increased risk of EPS events or prolactin levels. Primary: Irritability scores, as measured by the ABC-I, improved significantly in the risperidone high-dose group (P<0.001), but not in the risperidone low-dose group (P=0.164) compared with placebo. Separation between the risperidone high-dose and placebo groups was observed from day eight. Secondary: Response rates were significantly higher in the risperidone high-dose group (83%; P=0.004), but not in the low-dose group, compared with placebo. The number of patients showing much or very much improvement on the CGI-I scores, was significantly higher in the risperidone high-dose group (63%, P<0.001), but not in the low-dose group (77%, P=0.985), compared with placebo (15 %). For the ABC subscales, patients in the risperidone high-dose group showed significant improvement (P=0.019) on the hyperactivity subscale score, and patients in the risperidone low-dose group demonstrated significant improvement on the stereotypic behavior subscale scores

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
			week six	(P=0.008), compared with placebo. Neither risperidone group showed significant improvement on the inappropriate speech or social withdrawal subscale scores (risperidone low-dose group, P=0.716, high-dose group, P=0.511), compared with placebo.
				Consistent with the other efficacy measurements, only patients in the risperidone high-dose group showed significant improvement compared with placebo in the CY-BOCS compulsions subscale scores (risperidone high-dose group, P=0.003; risperidone low-dose group, P=0.454 vs. placebo).

				among patients receiving placebo, for a treatment difference of –4.40 (95% CI, –8.82 to 0.02; P=0.051). The mean CGI-I score at week 16 of phase 2 was 4.2 for aripiprazole and 4.8 for placebo, for a treatment difference of –0.62 (95% CI, –1.35 to 0.10; P=0.090). In addition, differences between aripiprazole and placebo in mean change at week 16 of phase 2 were seen in the following ABC subscales: ABC-hyperactivity (P=0.041), ABC-stereotypy (P=0.018), and ABC-inappropriate speech (P=0.013). A difference was not seen in the ABC-social withdrawal subscale (P=0.205). The week 16 mean treatment difference in the Caregiver Strain Questionnaire global score was more beneficial for aripiprazole, with a treatment difference of –1.2 (95% CI, –2.0 to –0.3). Results from the objective strain, subjective externalized strain, and subjective internalized strain subscales similarly favored aripiprazole. However, the mean treatment difference at week 16 of 6.3 points (95% CI, –0.63 to 13.22) on the PedsQL was similar for aripiprazole and placebo. Differences between aripiprazole and placebo for the combined PedsQL scale within individual age groups, and on the emotional, social, and cognitive functioning subscales were also not statistically significant.

Study 2 ²⁹⁰ (dossier) Brexpiprazole 1 mg once daily with antidepressant therapy vs brexpiprazole 3 mg once daily with antidepressant therapy vs placebo	inadequate response throughout the eight weeks of prospective antidepressants. MC, DB, PC, RCT Adult patients with MDD, with or without symptoms of anxiety, who had an inadequate response to prior antidepressant therapy (one to three courses) in the current episode and who also demonstrated an inadequate response throughout the eight weeks of	N=627 6 weeks	Primary: Change in MADRS total score from baseline to week six and improvement in functioning as measured by the SDS mean score Secondary: Not reported	Primary: Brexpiprazole 3 mg with antidepressant therapy had a greater reduction in MADRS total scores compared to placebo. LS mean change from baseline was -7.6 with brexpiprazole 1 mg compared to -8.3 with brexpiprazole 3 mg vs -6.3 with placebo. Placebo-subtracted difference for brexpiprazole 1 mg was -1.3 (95%CI,-2.7 to 0.13) and for brexpiprazole 3 mg was -2.0 (95% CI, CI:-3.4 to -0.5). Brexpiprazole 3 mg had greater improvement in SDS scale compared to placebo. Secondary: Not reported.
	prospective antidepressants.

				Generalized Anxiety Disorder:
				Significantly more patients in the quetiapine group experienced response

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				to treatment, defined as at least a 50% improvement in HAMD-A scores from baseline, compared to placebo. The pooled result indicates a 26% increase in the risk of a positive response at 8 weeks of therapy (RR, 1.26; 95%CI, 1.02 to 1.56).
				Olanzapine (RR, 6.67; 95%CI, 0.93 to 47.59) and risperidone (RR, 0.99; 95%CI, 0.78 to 1.25) were not associated with a significantly increased risk of a positive treatment response, compared to placebo.
				In head-to-head studies, quetiapine was comparable to paroxetine and escitalopram at 8 weeks (P value not reported).
				Obsessive Compulsive Disorder: Significantly more patients in the risperidone group experienced a positive response to treatment, compared to placebo (RR, 3.92; 95%CI, 1.26 to 12.13). Risperidone was associated with a 3.9-fold greater probability of responding compared to placebo; the NNT was estimated as 5.
				Olanzapine (RR, 1.00; 95%CI, 0.49 to 2.03) and quetiapine (RR, 2.36; 95%CI, 0.85 to 6.57) were not associated with significantly greater response rates compared to placebo.
				Other Conditions: Available evidence (6 trials) indicated that atypical antipsychotics are not effective in causing significant weight gain in patients with eating disorders.
				The level of evidence is mixed regarding personality disorders and moderate for an association of risperidone with improving post-traumatic stress disorder.
				Evidence does not support efficacy of atypical antipsychotics for substance abuse.

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				Safety: In the elderly patients, aripiprazole was associated with significantly increased odds of experiencing sedation. Olanzapine was associated with significantly increased odds of experiencing a cardiovascular event, increased appetite/weight gain, anticholinergic events, sedation, EPS (NNH=10), and urinary tract symptoms. Quetiapine was associated with significantly increased odds of experiencing sedation and urinary tract symptoms. Risperidone was associated with significantly increased odds of experiencing sedation, cardiovascular event, cerebrovascular event (for stroke, NNH=53), EPS (NNH=20) and urinary tract symptoms. In the non-elderly adult patients, aripiprazole was associated with significantly increased odds of experiencing increased appetite/weight gain, sedation, fatigue, akathisia, and EPS. Olanzapine was associated with significantly increased odds of experiencing sedation, increased appetite/weight gain, and fatigue. Quetiapine was associated with significantly increased odds of experiencing sedation, increased appetite/weight gain, fatigue, and EPS. Risperidone was associated with significantly increased odds of experiencing increased appetite/weight gain, sedation. Ziprasidone was associated with significantly increased odds of experiencing increased appetite/weight gain, sedation. Ziprasidone was associated with significantly increased odds of experiencing sedation and EPS. Secondary:

vs antidepressants	pregabalin or antidepressants in adult patients with generalized anxiety disorder, or phobias	Duration	MADRS, CGI, BSPS Secondary: Not reported	significantly improved in patients receiving quetiapine compared to placebo. Significantly more patients left the study early due to adverse events in the quetiapine group, compared to placebo (36.9 vs5.4%). Compared to placebo, quetiapine therapy was associated with a significantly increased risk of EPS adverse effects (2.5 vs 4.4%), weight gain (MD, 0.63 kg), and sedation (6.7 vs 24.5%). There was no statistically significant difference between quetiapine monotherapy and antidepressant groups in response rate, remission, global state (assessed via CGI scores), change in HAM-A scores, or change in MADRs scores (P value not reported). However, a larger percentage of patients in the quetiapine vs antidepressant groups left the study early due to adverse events (17.6 vs 8.9%, respectively). Comparing quetiapine add-on therapy to antidepressants and placebo adjunctive therapy in patients with generalized anxiety disorder, there were no statistically significant differences between groups in response,
				remission, global state, change in HAM-A, MADRS scores or percentage of patients leaving the study early (P value not reported). Comparing quetiapine monotherapy and placebo in patients with social phobia, there were no statistically significant differences between groups in response rate or global state (P value not reported). However, patients in the quetiapine groups exhibited lower BSPS scores at endpoint, indicating an improvement in anxiety symptoms (MD, 31.10; 95%CI, -85.41 to 147.61). Comparing olanzapine monotherapy and placebo in patients with social phobia, there were no statistically significant differences between groups in response rate, global state or percentage of patients leaving the study early (P value not reported). However, patients in the quetiapine groups exhibited lower BSPS scores at endpoint, indicating an improvement in anxiety symptoms (MD, -22.50; 95%CI, -35.25 to -9.75). There were no significant differences between groups in weight gain.

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				Comparing olanzapine add-on therapy to antidepressants and placebo adjunctive therapy in patients with generalized anxiety disorder, there were no statistically significant differences between groups in response, remission, or percentage of patients leaving the study early (P value not reported). In contrast, olanzapine add-on therapy was associated with a significant improvement from baseline in anxiety symptoms (HAM-A scores) and depressive symptoms (HAM-D), compared to adjunctive placebo therapy. Significantly more patients in the olanzapine group experienced weight gain and sedation.
				Comparing risperidone add-on therapy to antidepressants and placebo adjunctive therapy in patients with generalized anxiety disorder, there were no statistically significant differences between groups in response, remission, CGI scores, MADRS scores, or percentage of patients leaving the study early (P value not reported). In contrast, risperidone add-on therapy was associated with a significant improvement from baseline in anxiety symptoms (HAM-A scores) compared to adjunctive placebo therapy. There were no significant differences between groups in weight gain, sedation or EPS adverse events from baseline.

Atypical antipsychotics,	Randomized	5 to 24 weeks	psychotic	(anger, impulsivity, psychotic symptoms, interpersonal problems) as well

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
antidepressants, or mood stabilizers vs placebo	controlled studies in adults patients with borderline personality disorder		symptoms, interpersonal problems, anxiety, depression Secondary: Not reported	as in the treatment of comorbid conditions (depression, anxiety). Pooled data from placebo-controlled studies with olanzapine (N=631) demonstrate significant reduction of affective instability (SMC, -0.16; 95%CI, -0.32 to -0.01), anger (SMC, -0.27; 95%CI, -0.43 to -0.12), and psychotic symptoms (SMC, -0.18; 95%CI, -0.34 to -0.03). Anxiety symptoms were also reduced in one study with olanzapine. Ziprasidone was not demonstrated to exert significant effects on any
				Among the mood stabilizers, beneficial effects were found with divalproex sodium, lamotrigine and topiramate. Carbamazepine was not associated with a benefit in patients with borderline personality disorder. There was little evidence of efficacy with antidepressants. Only amitriptyline was associated with a significant reduction in depressive symptoms from baseline. No significant effect was found with fluoxetine and fluvoxamine. Secondary: Not reported
Mercer et al ⁸² Antipsychotics, antidepressants, or mood stabilizers	MA Randomized, controlled, double- blind studies in patients with BPD	N=735 5 to 24 weeks	Primary: Anger, symptoms of depression Secondary: Not reported	Primary: Mood stabilizers, with the exception of divalproic acid, were found to have the largest effect size for anger (-1.75; 95%CI, -2.77 to -0.74; P<0.001). The effect on anger was seen with lamotrigine, topiramate, and carbamazepine when used for up to 10 weeks. Divalproic acid and carbamazepine had a moderate effect on depression (-0.63; 95%CI, -0.99 to -0.27; P<0.001). Antidepressants, with the exception of tricyclic antidepressants, had a moderate effect size for anger (-0.74; 95%CI, -1.27 to -0.21; P<0.001), but exhibited a small effect on depression (-0.37; 95%CI, -0.69 to -0.05; P<0.01).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				Antipsychotics had a moderate effect size for anger (-0.59; 95%CI, -1.04 to -0.15; P<0.01), with aripiprazole associated with the largest effect size compared to other antipsychotics. Antipsychotics did not have a significant effect size for depression (-0.46; 95%CI, -0.94 to 0.03; P>0.05).

placebo	Alzheimer's type, vascular dementia, or a combination of the two		the CMAI total, total (verbal and physical) aggression, and total (verbal and physical)	Risperidone-treated patients (N=713) compared to the placebo group (N=426) also showed greater mean improvement at endpoint for total aggression (-5.0; 95% CI, -5.83 to -4.19 vs -1.8; 95% CI, -3.02 to -0.65; P<0.001) and total nonaggression (-6.8; 95% CI, -7.78 to -5.88 vs -4.5; 95% CI, -5.79 to -3.29; P<0.001), with the differences between group means (3.2 and 2.3 points, respectively) favoring risperidone.

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
			nonaggression scores, the BEHAVE-AD severity rating scale to assess behavioral symptom clusters including BEHAVE-AD total and psychotic-symptom subscale scores (paranoid/ delusional ideation and hallucinations) Secondary: CGI-C, CGI-S, safety assessments via adverse events, ESRS, MMSE, ECG and vital signs	The risperidone group had a significant mean improvement in total BEHAVE-AD score compared to the placebo group at the endpoint (-6.1; 95% CI, -6.72 to -5.42 vs -3.6; 95% CI, -4.43 to -2.76; P<0.001). The total mean score for the psychotic-symptom subscale also favored the risperidone group compared to placebo at endpoint (-2.1; 95% CI, -2.40 to -1.79 vs -1.3; 95% CI, -1.68 to -0.81; P=0.003). The paranoid and delusional subset also had greater mean improvement (0.7 points lower) in the risperidone group than the placebo group (-1.7; 95% CI, -1.95 to -1.45 vs -1.0; 95% CI, -1.31 to -0.65; P=0.002) as did the hallucinations subset (-0.4; 95% CI, -0.53 to -0.27 vs -0.3; 95% CI, -0.45 to -0.09 respectively; P=0.191). Scores on the BEHAVE-AD total scale, at all evaluation points, were significantly more improved in risperidone-treated patients compared to the placebo. Secondary: Compared to baseline, there was a 17.7% increase in the number of risperidone-treated patients rated by investigators as "moderately ill or less" at endpoint vs an 8.3% increase in the placebo group (N=428) as measured with the CGI-S scale (P<0.001). At endpoint, caregivers rated 22.9% more risperidone-treated patients vs 12.8% of placebo patients as "moderately ill or less" utilizing the CGI-S scale (P<0.01). CGI-C scale ratings by investigators and caregivers also favored the risperidone group with significant results vs placebo at endpoint compared to baseline. Investigators at endpoint ranked 65.2% of risperidone-treated patients were worse at endpoint compared to placebo (16.2 vs 25.1%, respectively; P<0.001, difference in distribution at endpoint). Caregivers rated 61.7% of risperidone patients as improved and 23.7% as worse vs 42.7% of placebo patients as improved and 33.3% as worse at endpoint compared to baseline (P<0.001, difference in distribution at endpoint).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				Risperidone-treated patients improved significantly more compared to those on placebo on the mean CMAI total scores in both Alzheimer's disease and vascular dementia subgroups, but not in the mixed group (-12.4 vs -6.8; P<0.001; -9.8 vs -5.4; P=0.019; and -11.6 vs -5.8; P=0.36; respectively). Similarly, more patients treated with risperidone had significantly better improvement in mean BEHAVE-AD total scores in both Alzheimer's disease and vascular dementia subgroups, but not in the mixed group (-6.3 vs -3.9; P<0.001; -5.5 vs -3.2; P=0.020; and -5.3 vs -2.7; P=0.084, respectively). Significant differences in CMAI total and BEHAVE-AD total scores favored the risperidone group at endpoint regardless of severity of dementia.
				The incidence of adverse events was similar in the risperidone group (84.3%) and placebo group (83.9%) across risperidone dose groups. Most commonly reported adverse events were injury, fall, somnolence, purpura, and urinary tract infections all of which were comparable between groups (except somnolence). Somnolence occurred in 22.4% of risperidone patients and 13.9% of placebo patients.
				There was no significant increase in risk of death associated with risperidone (relative risk vs placebo, 1.17; 95% CI, 0.63 to -2.81).

Olanzapine, quetiapine, or risperidone as adjunctive therapy to antidepressants vs placebo, in addition to antidepressants	Randomized controlled studies comparing adjunctive olanzapine, quetiapine or risperidone with placebo in adult patients with OCD	6 to 16 weeks	response (≥25% reduction in Y-BOCS scores), Y-BOCS, HAM-A, HAM-D, MADRS, CGI Secondary: Not reported	and placebo adjunctive therapies (OR, 0.28; 95%CI, 0.01 to 6.45). Moreover, there were no significant differences between groups in mental state (assessed via Y-BOCS) scores, anxiety symptoms (assessed via HAM-A) or depressive symptoms (assessed via HAM-D). Fewer patients discontinued the study early due to inefficacy in the adjunctive olanzapine group, compared to placebo (OR, 0.10; 95%CI, 0.01 to 0.98; P=0.05). Olanzapine adjunctive therapy was associated with significantly greater weight gain compared to placebo (OR, 2.30; 95%CI, 0.80 to 3.80). There was no significant difference in response rates between quetiapine and placebo adjunctive therapies (OR, 0.53; 95%CI, 0.27 to 1.05). In addition, quetiapine was associated with greater improvement from baseline in Y-BOCS scores and HAM-A scores. There was no significant difference between the groups in depressive symptoms, assessed via MADRS and HAM-D. Significantly more patients discontinued from the study early due to adverse effects in the quetiapine group than in the placebo group (OR, 4.48; 95%CI, 1.43 to 14.04). Quetiapine therapy was associated with significantly more weight gain and sedation than placebo. Risperidone adjunctive therapy was associated with significantly greater response rate, improved global state (CGI) scores, reduction in anxiety (HAM-A) and depressive (HAM-D) symptoms compared to placebo. There was no significant difference in Y-BOCS scores between groups. Sedation occurred more frequently in the risperidone group. The other adverse events were comparable between groups.

	randomized controlled trials, nonrandomized controlled trials, and cohort			olanzapine, quetiapine, risperidone, and ziprasidone were associated with significantly greater effect on manic symptoms compared to placebo. Medication adherence was significantly better with placebo compared to antipsychotic therapy. The overall strength of evidence of these outcomes was low.
	studies were included			Schizophrenia: Aripiprazole, olanzapine, paliperidone, quetiapine, and risperidone were associated with statistically significant improvements in CGI, positive and negative symptoms compared to placebo (strength of evidence: low). For both outcomes, risperidone was associated with greater efficacy over placebo compared to the other atypical antipsychotics.
				Clozapine, olanzapine, and risperidone were significantly more effective than haloperidol for CGI improvement. Medication adherence was comparable between patients who received olanzapine vs quetiapine, olanzapine vs risperidone, and atypical antipsychotics vs placebo. There was no significant difference between atypical antipsychotics and placebo in terms of reduction of suicide-related behavior. The overall strength of evidence of these outcomes was low.
				Behavioral Symptoms: In two studies, patients receiving risperidone experienced greater improvement in Aberrant Behavior Checklist (ABC) scores compared to placebo (strength of evidence: low).
				Adverse Events: In head-to-head study comparison, risperidone caused less dyslipidemia vs olanzapine; olanzapine caused fewer prolactin-related events vs risperidone; quetiapine and risperidone caused less weight gain vs olanzapine (strength of evidence: moderate). Furthermore, aripiprazole caused less dyslipidemia vs olanzapine or quetiapine; aripiprazole caused less weight gain vs olanzapine, quetiapine, or risperidone. There were no significant differences between atypical antipsychotics with respect to EPS, insulin resistance, and sedation (strength of evidence:

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
Anorexia				low). In placebo-controlled study comparison, risperidone caused less dyslipidemia vs olanzapine; olanzapine caused fewer prolactin-related adverse events vs risperidone; quetiapine and risperidone caused less weight gain vs olanzapine (strength of evidence: moderate). Secondary: Not reported
Leggero et al ⁹⁷ Olanzapine 1.25 mg to 12.5 mg daily as part of multimodal treatment (included psychotherapy, psychoeducation, assisted feeding, and prolonged control of somatic conditions)	PRO Girls, aged 9.6 to 16.3 years, diagnosed with anorexia	N=13 6 months	Primary: Body Mass Index (BMI), Children's Global Assessment Scale (CGAS), Clinical Global Impressions- Severity (CGI-S), Child Behavior Checklist (CBCL), Eating Attitude Test (EAT), Eating Disorder Inventory (EDI-2), Structured Inventory for Anorexic and Bulimic Syndromes-Expert Form (Hyperactivity) (SIAB-EX) Secondary: Not reported	Primary: At six months, olanzapine therapy was associated with a statistically significant improvement from baseline in BMI (P<0.001). At six months, olanzapine therapy was associated with a statistically significant improvement from baseline in CGAS (P<0.001). At six months, olanzapine therapy was associated with a statistically significant improvement from baseline in CGI-S (P<0.001). At six months, olanzapine therapy was associated with a statistically significant improvement from baseline in total CBCL scores (P=0.044). At six months, olanzapine therapy was associated with a statistically significant improvement from baseline in CBCL internalizing scores (P=0.034). At six months, olanzapine therapy was associated with statistically significant improvements from baseline in EAT-26 Total, Dieting, Bulimic, and Oral control scores (P<0.05). An improvement in EAT-26 of at least 50% was achieved in 7 out of 13 patients (responders). At six months, olanzapine therapy was associated with statistically significant improvements from baseline in two areas of EDI-2: Interoceptive Awareness and Impulsivity (P<0.05 for both).

				significant reduction from baseline in CDRS-R scores, compared to placebo (P>0.05).
				At four weeks, patients randomized to aripiprazole 15 mg and 30 mg daily therapy groups exhibited a statistically significant reduction from baseline in the ADHD-RS-IV total scores, compared to placebo (P<0.0001).
				Significantly more patients achieved treatment response after four weeks of therapy in the aripiprazole 10 mg (44.8%; P=0.0074) and 30 mg groups (63.6%; P<0.0001), compared to placebo (26.1%).
				Significantly more patients achieved disease remission after four weeks of therapy in the aripiprazole 10 mg (25%; P=0.0002) and 30 mg groups (47.5%; P<0.0001), compared to placebo (5.4%).
				At least one serious adverse event occurred in 5.1%, 2%, and 5.2% of patients receiving aripiprazole 10 mg, 30 mg, and placebo, respectively.
				No clinically significant trends in heart rate, blood pressure or ECG changes were observed among the groups.
				Mean weight gain from baseline was not statistically significant in the aripiprazole 10 mg daily (0.82 kg vs 0.56 kg; P=0.35) and aripiprazole 30 mg daily (1.08 kg vs 0.56 kg; P=0.13) groups, compared to placebo.
				There were no clinically significant changes from baseline in fasting serum glucose, total cholesterol, triglycerides, or HDL cholesterol (P value not reported).
				EPS events were reported by 23.5, 39.4, and 7.2% of the aripiprazole 10 mg daily, aripiprazole 30 mg daily, and placebo groups, respectively (P value not reported).

DelBello et al ¹⁰⁶ Quetiapine 300 to 600 mg daily vs placebo	DB, MC, PC, RCT Adolescents, aged 12 to 18 years, with a depressive episode associated with bipolar I disorder	N=32 8 weeks	Primary: Change in Children's Depression Rating Scale-Revised Version (CDRS-R) at 8 weeks Secondary: Change in CDRS-R over the study period, change in Hamilton Anxiety Rating Scale (HAM-A), Young Mania Rating Scale (YMRS), Clinical Global Impression- Bipolar Version Severity (CGI-BP-S), response, remission rate, adverse events	There were no significant differences between treatment groups in the reduction over time in CDRS or PANSS-P scores (P>0.05). The most common adverse events were sedation, nausea, headache, and gastrointestinal irritation. Sedation was significantly more common in patients receiving adjunctive quetiapine than placebo (P=0.03). There were no significant differences between the groups in change from baseline in QTc interval, platelet count, prolactin level, weight, EPS side effects, or liver function tests. Primary: At week six, both quetiapine and placebo groups exhibited statistically significant reductions in the CDRS-R scores from baseline (P<0.001). However, the difference between the quetiapine and placebo groups in the reduction of CDRS-R from baseline was not statistically significant (19 vs 20; P=0.89). Secondary: There was no statistically significant difference between the groups in the average rate of change in CDRS-R scores over the eight weeks of the study (P=0.11). Response rates were 67% and 71% in the placebo and quetiapine groups, respectively (P=1.0). Remission rates were 40% and 35% in the placebo and quetiapine groups, respectively (P=1.0). At week-6, both quetiapine and placebo groups exhibited statistically significant reductions in the HAM-A scores from baseline (P<0.05). However, the difference between the quetiapine and placebo groups in the reduction of HAM-A from baseline was not statistically significant (P=0.74).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				Quetiapine was associated with a statistically significant reduction from baseline in the YMRS scores (P=0.03), while the change from baseline in the placebo group was not statistically significant (P=0.09). There was no statistically significant difference in the change in YMRS scores from baseline between quetiapine and placebo (P=0.76). At week six, both quetiapine and placebo groups exhibited statistically significant reductions in the CGI-BP-S scores from baseline (P<0.005). However, the difference between the quetiapine and placebo groups in the reduction of CGI-BP-S from baseline was not statistically significant (P=0.9). The most commonly reported adverse events in the quetiapine group were gastrointestinal upset (65%), sedation (59%), and dizziness (41%). The only one of the above side effects that occurred at a significantly greater frequency in quetiapine-treated patients vs placebo was dizziness (P=0.04). Quetiapine-treated patients experienced significantly more frequent elevations in systolic, diastolic blood pressures, pulse and triglyceride level compared to placebo (P<0.05). Significant differences in QTc interval between groups were not observed (P=0.8). Quetiapine-treated patients gained an average of 2.3 kg while those receiving placebo gained 0.9 kg (P=0.12).
Pathak et al ²⁷⁷	DB, MC, PC, PG, RCT	N=284	Primary: Change from	Primary: The reduction from baseline in YMRS total score was significantly
Quetiapine 400 to 600 mg daily	Patients 10 to	3 weeks	baseline in YMRS total score	greater with quetiapine 400 mg (LSM change, -14.25±0.96; 95% CI, -16.15 to -12.35) and 600 mg (LSM change, -15.60±0.97; 95% CI, -17.15

	score ≥20 at baseline		(≥50% reduction in YMRS total score), remission (YMRS total score ≤12), CDRS-R, CGI-BP, CGAS and safety	Secondary: The treatment response rates were significantly higher with 400 and 600 mg of quetiapine compared to placebo after three weeks of treatment (55 and 56 vs 28%; P<0.001 for both compared to placebo). Remission rates were also significantly higher for patients treated with 400 mg (45%; P<0.01) or 600 mg (P<0.001) of quetiapine compared to placebo (23%). Overall, 23.7 and 19.8% of patients treated with quetiapine 400 or 600 mg rated themselves as 'very much improved' after three weeks compared to 13.2% of patients treated with placebo. Another 32.9, 45.7 and 20.6%, respectively, rated themselves as 'much improved'. Significant improvements in CGAS scores occurred in both quetiapine treatment groups compared to placebo (P<0.001 for both compared to placebo). The most common adverse events in quetiapine-treated patients were somnolence, sedation, dizziness and headache. Most events were mild to moderate in severity. Treatment discontinuation due to adverse events occurred in 15.8, 7.1 and 4.4% of patients treated with quetiapine 400, 600 mg or placebo, respectively. The mean change in body weight was 1.7, 1.7 and 0.4 kg for patients treated with quetiapine 400, 600 mg and placebo, respectively. An increase in body weight of at least seven percent from baseline occurred in 14.5, 9.9 and 0% of patients randomized to receive quetiapine 400, 600 mg or placebo, respectively. Potentially clinically significant shifts in total cholesterol, LDL, and TG concentrations were more frequent in the quetiapine treatment groups compared to placebo.

	monotherapy			SNAP-ADHD scores were significantly improved during the methylphenidate OROS phase of the study (P<0.001) and were further significantly improved following combination therapy with quetiapine (P<0.01). The only side effects reported at a significantly greater incidence during quetiapine administration than the methylphenidate OROS monotherapy phase were weight gain and increase in BMI (P<0.05). No EPS adverse events were reported.
Connor et al ¹¹⁸ Quetiapine 100 to 300 mg twice daily vs placebo	DB, PC, RCT Adolescents, aged 12 to 17, with a primary diagnosis of conduct disorder and exhibiting a moderate-to-severe degree of aggressive behavior, as documented by OAS score of ≥25 and CGI-S score ≥4	N=19 7 weeks	Primary: CGI-S, CGI-I Secondary: Parent-assessed Q-LES-Q quality of life, Overt Aggression Scale (OAS), conduct problems subscale of the Conners' Parent Rating Scale (CPRS-CP)	Primary: Quetiapine-treated patients experienced a statistically significant improvement in CGI-S scores from baseline, compared to placebotreated patients (P<0.05). Quetiapine-treated patients experienced a statistically significant improvement in CGI-I scores from baseline, compared to placebotreated patients (P=0.0006). Secondary: Quetiapine-treated patients were associated with a statistically significant improvement in Q-LES-Q quality of life scores from baseline, compared to placebo-treated patients (P=0.005). There were no statistically significant differences between groups in the change in OAS scores from baseline (P value not reported). There were no statistically significant differences between groups in the change in CPRS-CP scores from baseline (P value not reported). The only adverse events which were reported at a significantly greater frequency in the quetiapine group compared to placebo were decreased mental alertness, diminished emotional expression, and diminished facial expression (P<0.05).

Study and Drug Regimen	Study Design and	Sample Size and Study	End Points	Results
Ercan et al ¹¹⁹	Demographics OL, PRO	Duration N=8	Primary:	Weight gain of 2.3 kg was observed in the quetiapine group compared to a weight gain of 1.1 kg in patients receiving placebo (P=0.46). No significant differences in prolactin level was observed between groups (P=0.71). Primary:
Risperidone 0.125 mg (<20 kg weight) or 0.25 mg daily (>20 kg weight) initially up to a maximum of 1.50 mg daily	Preschool-aged children, 29 to 72 months of age, with conduct disorder and comorbid ADHD	8 weeks	Change from baseline in CGI-I, CGI-S, T-DSM-IV- S, response (defined as 30% reduction on the T- DSM-IV-S or CGI-I score of ≤2), adverse events Secondary: Not reported	Risperidone therapy was associated with a 78% reduction in CGI-S scores from baseline (P<0.001) at week-8 of therapy. Statistically significant improvement was also seen at week four of the study (P<0.001). All the children exhibited clinically significant improvements in CGI-S scores (much improved or very much improved) from baseline. At week eight, risperidone therapy was associated with a statistically significant reduction in CGI-I scores from baseline (P=0.002). The T-DSM-IV-S scores were significantly improved from baseline by 37.8 and 40.8 on both parental and clinical forms, respectively (P≤0.001). All the patients were classified as responders, on both the CGI and T-DSM-IV scales. There was no statistically or clinically significant weight gain among children receiving risperidone therapy. The mean weight gain from baseline was 0.3 kg (P=0.061). There was a significant seven-fold increase in prolactin levels from baseline among risperidone-treated patients (P<0.05). Except for one child who accidently received a high dose, risperidone therapy was not associated with neurological side effects or EPS.

	oppositional defiant disorder, who had participated in either of two 6-week, R, DB, PC trials		subscales, adverse events	helped others" (P<0.001). Risperidone-treated patients also experienced statistically significant improvements from baseline, compared to placebo, in the following N-CBRF social competence measures: "followed rules" and "stayed ontask" (P<0.01). Risperidone-treated patients experienced the most statistically significant improvements from baseline, compared to placebo, in the following N-CBRF problem behavior measures: "nervous or tense", "says no one likes him or her", "secretive, keeps things to self", and "talks too much or too loud" (P<0.001). Risperidone-treated patients also experienced statistically significant improvements from baseline, compared to placebo, in the following N-CBRF problem behavior measures: "exaggerates abilities or achievements", "feels others are against him/her", "lying or cheating", "steals", "too fearful or anxious", and "sulks, is silent or moody (P<0.01). There were no statistically significant differences between the groups in the following N-CBRF problem behavior measures: "overly anxious to please people", "self-conscious or easily embarrassed" and "worrying" (P>0.05). On the Hyperactivity N-CBRF problem behavior subscale, risperidone was associated with greater improvement from baseline compared to placebo in the following measures: "overactive, doesn't sit still", "restless, high energy level" (P<0.001), "easily distracted", "fails to finish things he/she starts", and "short attention span" (P<0.01). On the Self-Injury/Stereotypic N-CBRF problem behavior subscale, risperidone was associated with greater improvement from baseline compared to placebo in the following measures: "physically harms/hurts self on purpose" (P<0.01).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				On the Self-Isolated/Ritualistic N-CBRF problem behavior subscale, risperidone was associated with greater improvement from baseline compared to placebo in the following measures: "isolates self from others", "refuses to talk", and "odd repetitive behavior" (P<0.01). There was no statistically significant improvement from baseline between the groups in "disinterested or unmotivated", "rituals", and "shy/timid" behavior (P>0.05). On the Overly Sensitive subscale, the only significantly improved items was "easily frustrated" (P<0.001). "Sudden changes in mood" and "irritable" measures were also improved in the risperidone group compared to placebo (P<0.01). Headache and somnolence were the most frequently reported adverse events.
LeBlanc et al ¹²⁸ Risperidone solution 0.01 to 0.06 mg/kg/day vs placebo	Boys, aged 5 to 12 years, with or without comorbid ADHD, below average IQ scores, with either conduct disorder or oppositional defiant disorder, who had participated in either of two 6- week, R, DB, PC trials	N=163 6 weeks	Primary: Change from baseline in aggression score Secondary: Not reported	Primary: Compared to placebo, risperidone-treated patients experienced significantly greater mean decreases from baseline in the aggression score week one through week six of the study (P<0.001). At week six, aggression among risperidone-treated patients was reduced by 56.4% from baseline compared to a 21.7% reduction observed in the placebo group (P value not reported). 	and treated with adjunctive quetiapine					
Spielmans et al ²⁷⁸ Atypical antipsychotics used as adjunctive treatment (aripiprazole, olanzapine/ fluoxetine combination, quetiapine and risperidone) vs placebo	Patients with current MDD and an inadequate response to at least one course of antidepressant medication treatment	N=3,549 Up to 12 weeks	Primary: Remission (MADRS score ≤8, HAM-D score ≤7 or MADRS score of ≤10), treatment response (≥50% improvement from baseline in MADRS or HAM-D), quality of life and adverse events Secondary: Not reported	Primary: All four treatments significantly improved remission rates compared to placebo: aripiprazole (OR, 2.01; 95% CI, 1.48 to 2.73), olanzapine/fluoxetine (OR, 1.42; 95% CI, 1.01 to 2.0), quetiapine (OR, 1.79; 95% CI, 1.33 to 2.42) and risperidone (OR, 2.37; 95% CI, 1.31 to 4.30). The NNT was nine for all treatments except olanzapine/fluoxetine, for which the NNT was 19. The odds of a treatment response were significantly higher with aripiprazole (OR, 2.07; 95% CI, 1.58 to 2.72), olanzapine/fluoxetine (OR, 1.30; 95% CI, 0.87 to 1.93), quetiapine (OR, 1.53; 95% CI, 1.17 to 2.0) and risperidone (OR, 1.83; 95% CI, 1.16 to 2.88) compared to placebo. On measures of functioning and quality of life, atypical antipsychotics produced either no benefit or a very small benefit, with the exception of risperidone, which had a small-to-moderate effect on quality of life. Treatment was associated with several adverse events, including akathisia (aripiprazole), sedation (quetiapine, olanzapine/fluoxetine and olanzapine/fluoxetine), and weight gain (all four drugs, especially olanzapine/fluoxetine). Secondary: Not reported

	autism and behavioral problems, such as irritability, agitation, self-injurious behavior, or a combination of the above, mental age ≥18 months, CGI-S score ≥4 and ABC Irritability subscale score ≥18	Duration	ABC subtypes, CY-BOCS, adverse events	improvement from baseline in the mean CGI-I scores compared to placebo (P<0.005). Compared to placebo, aripiprazole 15 mg daily was associated with statistically significant improvements in the following ABC subscales: ABC stereotype, ABC Hyperactivity, and ABC Inappropriate Speech (P≤0.05). Compared to placebo, aripiprazole 5 mg and 10 mg daily doses were associated with statistically significant improvements in the following ABC subscales: ABC stereotype and ABC Hyperactivity (P≤0.05). ABC Lethargy/Social Withdrawal subscale was not significantly changed in any of the three aripiprazole dose groups, compared to placebo (P>0.05). Compared to placebo, significant improvements in CGI-S were seen in aripiprazole 10 mg and 15 mg groups (P≤0.05). A significant improvement in CY-BOCS was only seen in the aripiprazole 15 mg group (P≤0.05). At week-8, response rate was significantly greater in the aripiprazole 5 mg group, compared to placebo (55.8 vs 34.7%; P=0.34). However, there were no significant differences in response rate between patients receiving placebo and aripiprazole 10 mg or 15 mg daily. The most common adverse events leading to discontinuation were sedation, drooling, and tremor. No one in the aripiprazole groups discontinued due to inadequate efficacy. EPS adverse events were reported in 11.8% of the placebo group and 22-23% of the aripiprazole group. Significantly more patients in the aripiprazole groups experienced weight gain compared to the placebo group (1.3-1.5 vs 0.3 kg; P<0.05).

	with autism spectrum disorder		events Secondary: Not reported	six months and one year, respectively. Weight gain was the most frequently observed adverse event in both groups, followed by somnolence, aggression, and abnormal movements. Among patients five years of age or younger, 69% of patients met criteria for treatment success at 6 months. Risperidone was used as a first-line agent in 70% of patients in this age group. Prior medications included clonidine, guanfacine, and valproic acid. Somnolence was the most robust predictor of treatment failure. Secondary: Not reported
Aman et al ¹⁴⁷ Risperidone 0.5-3.5 mg/day in two divided doses vs placebo	DB, PC Individuals aged 5-17 diagnosed with autism according to DSM-IV criteria	N=101 Double-blind comparison: 8 weeks Open label extension: 16 weeks	Primary: Laboratory values, vital signs, height and weight, adverse events Secondary: Not reported	Primary: After the eight week comparison, statistically significant changes in laboratory findings were found for red blood cell, neutrophil, and lymphocyte counts and for SGPT/SGOT (P values not reported). An elevated white blood cell count in a patient was the only abnormal laboratory findings reported at the four month extension. Tired during the day (P<0.0001), excessive appetite (P<0.0001), difficulty waking (P=0.05), excessive saliva or drooling (P=0.04), and dizziness or loss of balance (P=0.04) were reported significantly more frequently in the risperidone group. Difficulty falling asleep (P=0.02) and anxiety (P=0.05) were significantly less in the risperidone group compared to placebo. Significant weight gain was noted in the risperidone group (P<0.001). There was no significant difference between placebo and risperidone in vital signs (P=0.15-0.65).

Aman et al ¹⁴⁸ Risperidone 0.5-3.5 mg/day in two divided doses vs placebo	SA (study by Aman et al 2005) Individuals aged 5-17 diagnosed with autism according to DSM-IV criteria	N=38 Double-blind comparison: 8 weeks	Primary: Cognition Secondary: Not reported	Primary: Risperidone was not associated with a decline in performance. The following performance tasks were better executed by patients receiving risperidone than placebo: cancellation task and verbal learning task. There were no significant differences between groups in performance in the Pegboard (hand-eye coordination) or the Analog Classroom (timed math test) tasks (P value not reported). Secondary: Not reported
Aman et al ¹⁴⁹ Risperidone, 0.25-1.75 mg daily (14-20 kg), 0.5-2.5 mg daily (20-45 kg)* (Medication group) vs combined treatment with risperidone, dosed same as above, and parent training in behavior management (COMB group) *Patients who did not exhibit a positive response to risperidone at 8 weeks were switched to aripiprazole	PG, MC, RCT Children, aged 4 to 13 years, with PDD, ≥18 on the Irritability subscale of parent-rated ABC, CGI severity score ≥4, not taking psychotropic drugs for at least 2 weeks, IQ≥35 or mental age ≥18 months	N=124 24-week	Primary: Home Situations Questionnaire (HSQ) severity score Secondary: ABC Irritability, ABC Stereotypic, ABC Hyperactivity, ABC Social Withdrawal, ABC Inappropriate Speech, Children's Yale-Brown Obsessive Compulsive Scale (CY-BOCS), adverse events	Primary: After 24 weeks of therapy, HSQ scores significantly decreased by 71% in the COMB group compared to a 60% reduction from baseline observed in the medication group (P=0.006). Secondary: After 24 weeks of therapy, improvement in ABC Irritability subscale scores from baseline was significantly greater among patients randomized to COMB therapy compared to medication alone (P=0.01). After 24 weeks of therapy, improvement in ABC Stereotypic subscale scores from baseline was significantly greater among patients randomized to COMB therapy compared to medication alone (P=0.04). After 24 weeks of therapy, improvement in ABC Hyperactivity subscale scores from baseline was significantly greater among patients randomized to COMB therapy compared to medication alone (P=0.04). After 24 weeks of therapy, there were no statistically significant differences between groups in improvement from baseline in the following endpoints: ABC Social Withdrawal (P=0.78), ABC

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				Inappropriate Speech (P=0.20), and CY-BOCS (P=0.62). The only statistically significant difference between groups in terms of adverse events was with insomnia, which occurred more frequently in the medication alone group (P=0.04).
Luby et al ¹⁵⁰ Risperidone 0.5-1.5 mg in two divided doses per day vs placebo	DB, PC, RCT Preschool children 2.5 to 6 years of age with autism or pervasive developmental disorder not otherwise specified according to DSM-IV criteria	N=25 6 months	Primary: CARS, GARS Secondary: Physiological measures, adverse events	Primary: No statistically significant difference was seen between the two treatment groups on any of the outcome measures of interest when differences in baseline developmental characteristics were accounted for. There was no significant difference between the two treatment groups in the effectiveness on anxiety (P=0.056). Secondary: There was a significant difference between risperidone and placebo in mean weight gain (2.96 kg compared to 0.61 kg; P=0.008) and prolactin change (33.38 ng/mL compared to 11.11 ng/mL; P=0.015). There was no significant difference in adverse events between groups (P value not reported).
McCracken et al ¹⁵¹ Risperidone 0.5 to 3.5 mg daily vs	DB, MC, PC, RCT Children and adolescents, aged 5 to 17	N=101 8 weeks	Primary: ABC Irritability score, response rate (defined as >25% increase in ABC irritability	Primary: At week eight, risperidone-treated patients exhibited a 56.9% reduction in the mean ABC Irritability score from baseline, compared to a 14.1% reduction observed in the placebo group (P<0.001). A positive response was noted in 69 and 12% of patients randomized to
placebo	years, diagnosed with autistic disorder with tantrums, aggression, self- injurious behavior, or a combination of		score and a ČGI-I rating of much improved or very much improved) Secondary: ABC Social Withdrawal, ABC	risperidone and placebo therapy, respectively (P<0.001). In 2/3 of patients with a positive response at eight weeks, the benefit was maintained at six months. Secondary: At week eight, risperidone-treated patients exhibited a significantly greater improvement in the mean ABC Social Withdrawal score from baseline, compared to the placebo group (P=0.03).

Study and Drug Regimen	Study Design and	Sample Size and Study	End Points	Results
	above, exhibiting a mental age of ≥18 months, weighing ≥15 kg	Duration	Stereotype, ABC Hyperactivity, ABC Inappropriate Speech, CGI-I, adverse events	At week eight, risperidone-treated patients exhibited a significantly greater improvement in the mean ABC Stereotype score from baseline, compared to the placebo group (P<0.001). At week eight, risperidone-treated patients exhibited a significantly greater improvement in the mean ABC Hyperactivity score from baseline, compared to the placebo group (P<0.001). At week eight, risperidone-treated patients exhibited a significantly greater reduction in the mean ABC Inappropriate Speech score from baseline, compared to the placebo group (P=0.03). At week eight, the proportion of patients whose behavior was rated as much improved on the CGI-I scale differed between the two groups by 64%, in favor of risperidone (P<0.001). Risperidone group gained significantly more weight compared to the placebo group (2.7 vs 0.8 kg; P<0.001). Increased appetite, fatigue, drowsiness, dizziness, and drooling were more common in the risperidone group compared to placebo (P<0.05).
Miral et al ¹⁵² Risperidone dosed 0.01 mg/kg up to 0.08 mg/kg daily vs haloperidol dosed 0.01 mg/kg up to 0.08 mg/kg daily	DB, RCT Children and adolescents, aged 8 to 18, with autistic disorder	N=30 12 weeks	Primary: CGI-I, Ritvo- Freeman Real Life Rating Scale (RF- RLRS), ABC, Turgay DSM-IV Pervasive Developmental Disorder Rating Scale (TPDDRS), adverse events Secondary: Not reported	Primary: The change in CGI-I scores from baseline was not significantly different between the two study groups at week-12 (P=0.11). At week-12, there was no statistically significant difference between groups in the change from baseline in any of the RF-RLRS subscale scores (P>0.05). Risperidone was associated with significant improvement from baseline in all RF-RLRS subtypes; whereas haloperidol was associated with a significant improvement in all but one measure (language subscale). While the change from baseline in ABC scores was significant in both groups (P<0.005), risperidone therapy was associated with significantly greater improvement compared to haloperidol (P=0.0062).

Study and Drug Regimen	y Design Sample Size and Study ographics Duration	End Points	Results
Risperidone dosed up to 0.08 mg/kg daily Childra adoles		Primary: CGI-I, Ritvo- Freeman Real Life Rating Scale (RF- RLRS), ABC, Turgay DSM-IV Pervasive Developmental Disorder Rating Scale (TPDDRS), adverse events Secondary: Not reported	While the change from baseline in TPDDRS scores was significant in both groups (P<0.005), risperidone therapy was associated with significantly greater improvement compared to haloperidol (P=0.0052). Patients receiving haloperidol experienced significantly more EPS events than at baseline (P=0.0477); whereas there was no significant increase in EPS events in the risperidone group (P value not reported). Haloperidol therapy was associated with increased heart rate, weight, height and prolactin (P<0.05). Risperidone therapy was associated with increased weight, height, HbA _{1c} and prolactin (P<0.05). The only statistically significant differences between groups in terms of adverse events were increases in ALT with haloperidol therapy and increases in prolactin with risperidone therapy (P<0.05). Secondary: Not reported Primary: Risperidone therapy was associated with significantly greater improvement from baseline in CGI-I scores compared to haloperidol (P=0.0186). At week-24, the change from baseline in RF-RLRS sensory-motor subscale scores was statistically significant in the risperidone group (P=0.018), but not in the haloperidol group (P=0.16). Risperidone therapy was associated with significantly greater improvement from baseline in RF-RLRS language subscale scores compared to haloperidol (P=0.0414). There were no statistically significant differences between groups in the change from baseline in the other RF-RLRS subscales (P>0.05).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				significant in the risperidone group (P=0.0029), but not in the haloperidol group (P=0.53). However, there was no statistically significant difference in the change in ABC scores from baseline between the two groups (P=0.07). Both risperidone and haloperidol groups experienced a statistically significant improvement in TPDDRS scores from baseline at week-24 of therapy (P<0.05). At week-24, both groups experienced statistically significant weight gain from baseline. However, haloperidol was associated with more weight
				gain than risperidone therapy (P=0.04). At week-24, there was no statistically significant difference between the groups in serum prolactin levels (P=0.55) or EPS adverse events (P value not reported). Secondary: Not reported
Nagaraj et al ¹⁵⁴ Risperidone 0.5 mg daily for the first week then 1 mg daily vs	DB, PC, RCT Children 2-9 years of age diagnosed with autism according to	N=40 6 months	Primary: CARS, CGAS, global impression of parents, analysis of parents questionnaire	Primary: In the risperidone group 63% of the patients demonstrated an improvement of at least 20% from baseline in their CARS score compared to none of the patients in the placebo group (P<0.001). In the risperidone group 89% of the patients demonstrated an improvement of at least 20% from baseline in their CGAS score
placebo	DSM-IV criteria		Secondary: Safety	compared to 9% of the patients in the placebo group (P=0.035). There was no significant difference between the treatment groups in the global impression of the parents (P value not reported). In the analysis of the parent questionnaire risperidone significantly improved functioning in the domains of social responsiveness (P=0.014), nonverbal communication (P=0.008), decreased symptoms of hyperactivity (P=0.002), and aggression and irritability (P=0.016). No

Malone et al ¹⁵⁵ Ziprasidone 20 mg to 160 mg daily	OL Adolescents, aged 12.1 to 18.5 years, with autism and a CGI-S score of >4	N=12 6 weeks	Primary: CGI Secondary: ABC subtypes, Children's Psychiatric Rating Scale (CPRS) subtypes, adverse events	significant difference was reported with regard to restricted interests, emotional interaction or verbal communication. Secondary: An increased appetite, mild sedation in 20% and transient dyskinesias in 10% were reported (P value not reported). In the risperidone group, the mean weight gain was 2.81 kg, an increase of 17% compared to 1.71 kg, an increase of 9.3% in the placebo group, a difference that was statistically significant (P value not reported). Primary: At week six, 75% of patients experienced a response on the CGI scale. The change from baseline in CGI-S was not statistically significant (P=0.07). Secondary: Statistically significant improvement from baseline was seen in respect to the irritability and hyperactivity subtypes of the ABC (P≤0.05). However, the other ABC subtypes (lethargy/social withdrawal, stereotypic behavior and inappropriate speech) were not significantly changed from baseline (P>0.05). Statistically significant improvement from baseline was only seen in respect to the autism measure of the CPRS (P=0.009). There were no significant changes from baseline in the anger, hyperactivity, or speech deviance measures of the CPRS (P>0.05). Ziprasidone was weight neutral, significantly increased QTc by a mean of 14.7 msec (P=0.04), significantly decreased baseline total cholesterol levels (P=0.04), was not associated with significant changes in LDL, HDL cholesterol, triglycerides, or prolactin levels.

At week six, patients randomized to the aripiprazole 10 mg and 30 mg groups experienced a statistically significant improvement in the CGI severity and improvement scores from baseline compared to placebo (P<0.05). At week six, patients randomized to the aripiprazole 10 mg and 30 mg groups experienced a statistically significant improvement in the Children's Global Assessment Scale scores from baseline compared to placebo (P=0.006 and P=0.005, respectively). At week six, patients randomized to the aripiprazole 10 mg and 30 mg groups experienced a statistically significant improvement in the Pediatric Quality of Life Enjoyment and Satisfaction Questionnaire overall scores from baseline compared to placebo (P=0.005 and P=0.003, respectively). However, there was no statistically significant difference between the two aripiprazole groups and placebo in the change from baseline of the Pediatric Quality of Life Enjoyment and Satisfaction Questionnaire total scores (P>0.05).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				At week six, 53% and 56%, respectively, of patients in the aripiprazole 10 mg and 30 mg treatment groups achieved disease remission, compared to 35% of patients in the placebo group (P=0.02 and P=0.003, respectively).
				The most frequently reported treatment-emergent adverse effects that occurred at an incidence of at least 5% were EPS disorder (5% with placebo, 13% with aripiprazole 10 mg, 22% with aripiprazole 30 mg), somnolence (6% with placebo, 11% with aripiprazole 10 mg, 22% with aripiprazole 30 mg), and tremor (2% with placebo, 2% with aripiprazole 10 mg, 12% with aripiprazole 30 mg).
				The most common types of experienced EPS events were parkinsonism (7% with placebo, 15% with aripiprazole 10 mg, 30% with aripiprazole 30 mg) and akathisia (6% with placebo, 6% with aripiprazole 10 mg, 12% with aripiprazole 30 mg).
				Patients randomized to the aripiprazole 30 mg group gained an average of 0.2 kg from baseline compared to a weight loss of an average of 0.8 kg in the placebo group (P=0.009). The 10 mg aripiprazole group did not exhibit changes in weight.
				There were no clinically significant differences among treatment groups in glucose or lipid measures.
				Both aripiprazole treatment groups exhibited statistically significant reductions in prolactin levels compared to placebo (P<0.005).
				There were no statistically significant differences among groups with respect to time to discontinuation (P>0.05).

Antipsychotics (aripiprazole 10 to 20 mg daily, clozapine 200 to 500 mg daily, haloperidol 3 to 8 mg daily, olanzapine 10 to 20 mg daily, quetiapine 250 to 450 mg daily, risperidone 3 to 6 mg daily)	Children and adolescents, 10 to 17 years, with schizophrenia or schizoaffective disorder	3 years to11 years	Response rate, PANSS, CGI scores, adverse events Secondary: Not reported	At year three of follow-up, clozapine therapy was associated with the highest response rate (81.5%), followed by aripiprazole (75%), quetiapine (50%), risperidone (37.5%), olanzapine (8.3%), and finally haloperidol (10%). Response rates were significantly greater among patients who had received clozapine compared to risperidone (P<0.01) or olanzapine (P<0.001). A comparison of the degree of clinical improvement at the five years of follow-up showed a statistically greater improvement in PANSS and CGI scores in patients treated with clozapine compared to either risperidone or olanzapine treatment (P<0.05). At three-year through 11-year follow-up, clozapine was associated with a significantly greater improvement in GAF scores compared to the other antipsychotics, combined (P<0.05). Excessive weight gain was observed in 60% of patients receiving olanzapine, 35.5% and 28.6% of patients receiving risperidone and clozapine, respectively. After five years of therapy, olanzapine was associated with the greatest rate of discontinuations due to adverse events (33.3%), followed by risperidone (28.1%), clozapine (16%), and aripiprazole (14.3%). Of note all the patients receiving olanzapine discontinued therapy by year-five of follow-up. The reasons for discontinuing olanzapine were weight gain in 25% and amenorrhea in 16.7%. The reasons for discontinuing risperidone were weight gain in 6%, amenorrhea in 6%, neurodysleptic crisis in 6%, and adenoma, parkinsonism, or seizures in 1%, each. The reasons for discontinuing clozapine were weight gain in 3.6%, neutropenia in 7.1% and seizures in 3.6%. Only one patient discontinued aripiprazole therapy and that was due to anorexia.

				Patients receiving aripiprazole did not experience any clinically significant changes in laboratory parameters, including BMI.
Lyon et al ¹⁷⁷	OL, PRO	N=10	Primary: YGTSS subscales,	Primary: Aripiprazole therapy was associated with statistically significant
Aripiprazole 1.25 mg to 13.75 mg daily	Children and adolescents,	10 weeks	CGI-Tics	reduction from baseline in YGTSS motor (-6.09; P=0.005) and vocal tic scores (-5.36; P=0.008).
	aged 7 to 18, with Tourette's Disorder or		Secondary: Children's Global Assessment Scale	Aripiprazole therapy was associated with statistically significant reduction from baseline in YGTSS total tic (-11.45; P=0.003) and global

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
	chronic motor tic disorder, had failed trials with clonidine, guanfacine or neuroleptic medication in the past, tics caused significant distress, and had normal intelligence		(C-GAS), Children's Depression Rating Scale (CDRS-R), Clinical Global Impressions Scale for Obsessive Compulsive Disorder (CGI- OCD), CGI-ADHD, CY-BOCS, Multidimensional Anxiety Scale for Children (MASC), Attention Deficit Hyperactivity Disorder Rating Scale (ADHD-RS)	severity scores (-28.09; P=0.003). Aripiprazole therapy was associated with statistically significant reduction from baseline in CGI-Tic severity scores (-1.27; P=0.004). On the CGI-Tic improvement scale, 91% of patients had a rating of one ("very much improved") or two ("much improved") at the end of the study. Secondary: Aripiprazole therapy was associated with statistically significant improvements from baseline in the C-GAS scores, both attention and hyperactivity/impulsivity measures of ADHD-RS, CGI-OCD, and the obsession subscale of CY-BOCS (P<0.05). Aripiprazole therapy was not associated with statistically significant improvements from baseline in CDRS-R, CGI-ADHD, MASC total score, and the compulsion subscale of the CY-BOCS (P>0.05). Most frequently reported adverse events were appetite increase and weight gain, mild EPS effects, headaches, and tiredness/fatigue. Patients gained an average of 2.16 lbs over the course of the study, which was not significantly different from baseline (P=0.286). There were no significant changes from baseline in ECGs (P value not reported). Patients experienced a significant reduction in prolactin levels (P=0.03).
Murphy et al ¹⁷⁸ Aripiprazole 1.25 mg to 7.5 mg daily	OL Children and adolescents, aged 8 to 17 years, with a primary diagnosis of a chronic tic	N=16 6 weeks	Primary: Yale Global Tic Severity Scale (YGTSS), CY- BOCS, CGI-Tic Secondary: CGI-OCD, Abbreviated	Primary: Aripiprazole therapy was associated with statistically significant reduction from baseline in YGTSS motor (-8.9; P<0.0001), phonic (-8.6; P<0.0001), and total tic scores (-17.5; P<0.0001). Aripiprazole therapy was associated with statistically significant improvement from baseline in CY-BOCS Obsessions, Compulsions, and total OCD subscale scores (P<0.005).

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
	disorder		Symptom Questionnaire for Parents (ASQ-P), CDRS, adverse events	Aripiprazole therapy was associated with statistically significant improvement from baseline in CGI-Tic Severity (-1.75; P<0.0001) and Improvement scores (2.5; P<0.0001). Secondary: Aripiprazole therapy was associated with statistically significant improvement from baseline in CGI-OCD Severity (-1.1; P<0.0001) and Improvement scores (2.0; P<0.0001). Aripiprazole therapy was associated with statistically significant reduction from baseline in ASQ-P scores (P=0.012). Aripiprazole therapy was associated with statistically significant reduction from baseline in CDRS scores (P=0.002). Aripiprazole was associated with an average weight gain of 2.3 kg overall (P<0.003), and 4.1 kg among patients concurrently receiving a selective serotonin reuptake inhibitor (SSRI). There were no statistically significant changes in metabolic test results or ECG (P value not reported).
Seo et al ¹⁷⁹ Aripiprazole 2.5 mg to 15 mg daily	OL, PRO Children and adolescents, aged 7 to 19 years, with Tourette Disorder or chronic tic disorder	N=15 12 weeks	Primary: Yale Global Tic Severity Scale (YGTSS) Secondary: CGI-I, CGI-S, adverse events	Primary: Aripiprazole therapy was associated with statistically significant improvement in YGTTS motor tic, phonic tic, and total tic scores compared to baseline (P<0.001 for all). Secondary: At week-12, aripiprazole therapy was associated with statistically significant improvement from baseline in CGI-I and SGI-S scores, beginning at week-3 of the study (P<0.001 for both). Nausea and sedation were the most frequently reported adverse events. There was no statistically significant change from baseline in BMI (P=0.749).
McCracken et al ¹⁸⁰	OL, PRO	N=12	Primary: YGTSS motor tic,	Primary: Aripiprazole was associated with statistically significant improvements in

Study and Drug Regimen	Study Design and	Sample Size and Study	End Points	Results
	Demographics	Duration		
Olanzapine 2.5 mg up to a maximum of 20 mg daily	Children and adolescents, aged 7 to 17 years, with Tourette Disorder, CGI ≥4 (moderately ill) Note: all patients had at least one comorbid condition, most commonly ADHD	6 weeks	YGTSS vocal tic, YGTSS total tic severity scores Secondary: Swanson, Nolan and Pelham Questionnaire (SNAP-IV), Overt Aggression Scale (OAS), Multidimensional Anxiety Scale for Children (MASC) Child, MASC Parent scores, adverse events	all measures of the YGTSS motor tic scale, including the total motor tic severity score (P<0.05 for all). Aripiprazole was associated with a statistically significant improvement in the YGTSS vocal tic interference scores (P<0.05), though the other measures of this category were not significantly changed from baseline. Aripiprazole was associated with statistically significant improvements in most measures of the YGTSS total tic scale, including the total tic severity score (P<0.05 for all). The only measures that were not significantly changed from baseline were YGTSS total tic number and complexity (P>0.05). Secondary: Significant changes from baseline were noted in the YGTSS Overall Impairment and Global Severity scores (P<0.001). Significant changes from baseline were noted in all of the following categories of SNAP IV: ADHD Inattention, ADHD Hyperactivity/Impulsivity, ODD, Inattention/overactivity, Aggression/Defiance, and Conners' Index (P<0.01). Significant changes from baseline were also noted in the OAS number of episodes scores and MASC Child Physical Symptoms scores (P<0.05). No significant changes from baseline were observed in the remaining categories of OAS or MASC-Child, as well as the MASC-Parent scores (P>0.05). Olanzapine therapy was associated with a statistically significant weight gain from baseline (P<0.001). The mean percentage change from baseline to week six was 8.4 (P<0.001). Drowsiness/sedation was also frequently reported.

Miscellaneous Mental Health De Capone et al 184 Risperidone 0.25 mg to 1.5 mg once daily at bedtime	syndrome and chronic tic disorders		Primary: ABC subscales, adverse events Secondary: Not reported	blind videotape tic counts (P=0.039). There were no clinically significant EPS adverse events. Mild transient somnolence was the most common adverse event. Secondary: Not reported Primary: Risperidone therapy was associated with a statistically significant improvement in the ABC composite score from baseline (P<0.001). The greatest improvement from baseline occurred in regard to the following ABC subtypes: lethargy, stereotypy, and hyperactivity (P<0.001). However, the other two ABC subtypes were also significantly improved from baseline (P<0.05). Children with both disruptive behavior and self-injury were associated with the greatest improvement in symptoms with risperidone therapy. Among patients with pre-existing sleep disturbances, 88% experienced an improvement in sleep quality. Risperidone therapy was associated with an average weight gain of 2.8 kg.
				Secondary: Not reported
Erickson et al ¹⁸⁵ Aripiprazole, 9.8 mg daily on average	OL, PRO Patients, aged 6 to 25, with Fragile X syndrome (FXS) Note: FXS is a	N=12 12 weeks	Primary: Treatment response (defined as CGI-I score of much improved or very much improved and a >25% improvement	Primary: Aripiprazole therapy was associated with a treatment response in 87% of patients. Discontinuations from the study occurred in two of 12 patients and were due to the following adverse events: akathisia, drooling, and tiredness. There were no significant changes from baseline in weight or laboratory

Castro-Fornieles et al ¹⁸⁷ Antipsychotic agents (risperidone, quetiapine, olanzapine) administered at varying doses	symptom-free periods of greater than 2 months, and no psychotropic use within 6 months PRO, OL Children and adolescents, aged 9 to 17 years, with a first psychotic episode attributed to a psychotic disorder not otherwise specified, schizophreniatype disorder, depressive disorder with psychotic symptoms, and bipolar mania with psychotic features	N=110 6 months	Primary: PANSS, CGI, Disability Assessment Scale (DAS), Global Assessment Functioning (GAF), adverse events Secondary: Not reported	Primary: At six months of follow-up, PANSS total scores were significantly improved from baseline in patients treated with risperidone, quetiapine or olanzapine (P≤0.001). There were no significant differences among the three treatment groups in the reduction of PANSS total scores from baseline (P=0.876). At six months of follow-up, PANSS positive symptom scores were significantly improved from baseline in patients treated with risperidone, quetiapine or olanzapine (P≤0.001). There were no significant differences among the three treatment groups in the reduction of PANSS positive symptom scores from baseline (P=0.681). At six months of follow-up, PANSS negative symptom scores were not significantly changed from baseline in the risperidone group (P=0.53), but were significantly improved from baseline in patients treated with quetiapine or olanzapine (P<0.01). There were no significant differences among the three treatment groups in the reduction of PANSS negative symptom scores from baseline (P=0.195). At six months of follow-up, PANSS general scores were significantly improved from baseline in patients treated with risperidone, quetiapine or olanzapine (P≤0.001). There were no significant differences among the three treatment groups in the reduction of PANSS general scores from baseline (P=0.741).
				At six months of follow-up, CGI scores were significantly improved from baseline in patients treated with risperidone, quetiapine or olanzapine

Study and Drug Regimen	Study Design and	Sample Size and Study	End Points	Results
	Demographics	Duration		
	<u> </u>			(P≤0.001). There were no significant differences among the three treatment groups in the reduction of CGI scores from baseline (P=0.237).
				At six months of follow-up, DAS scores were significantly improved from baseline in patients treated with risperidone, quetiapine or olanzapine (P<0.05). There were no significant differences among the three treatment groups in the reduction of DAS scores from baseline (P=0.075).
				At six months of follow-up, GAF scores were significantly improved from baseline in patients treated with risperidone, quetiapine or olanzapine (P<0.05). There were no significant differences among the three treatment groups in the reduction of GAF scores from baseline (P=0.069).
				Olanzapine therapy was associated with significantly greater weight gain (11.7 kg) from baseline compared to either risperidone (6.1 kg; P=0.02) or quetiapine (6.0 kg; P=0.04).
				Risperidone was associated with a significantly greater frequently of neurological side effects, compared to olanzapine (P=0.022). Hypokinesia was the most frequent neurological adverse event reported in association with risperidone therapy and occurred at a significantly greater incidence compared to quetiapine and olanzapine (50 vs 13.3 vs 15.4%, respectively; P=0.001).
Sikich et al ¹⁸⁸	DB, PG, RCT	N=50	Primary: BPRS-C,	Primary: All treatment groups experienced a statistically significant improvement

to a maximum daily dose of 6 mg vs haloperidol 1 to 5 mg daily, up to a maximum daily dose of 8 mg			reduction in BPRS-C total score), adverse events	total scores did not significantly differ among the groups (P=0.416). CPRS-positive scores were significantly improved from baseline in all three treatment groups (P<0.05), though the difference in CPRS-positive scores was not statistically significant among the three groups (P=0.252). CPRS-negative scores were significantly improved from baseline only in the risperidone group (P=0.005); however, there was no significant difference among the three groups (P=0.47). CGI-S scores were significantly improved from baseline in the risperidone and olanzapine treatment groups (P<0.01), though the difference in CGI-S scores was not statistically significant among the three groups (P=0.064). CGI-I scores were significantly improved from baseline in the risperidone and olanzapine treatment groups (P=0.018), though the difference in CGI-I scores was not statistically significant among the three groups (P=0.15). Treatment response was achieved by 88% of patients in the olanzapine group, 74% of patients in the risperidone group, and 53% of patients in the haloperidol group. The difference among the three groups was not statistically significant (P=0.12). However, there were differences in the mean time to response among the three antipsychotic groups: 1.6 weeks with olanzapine, 2.3 weeks with risperidone, and 2.4 weeks with haloperidol (P<0.045). While more than 50% of patients treated with either olanzapine or risperidone experienced Parkinsonian symptoms, the incidence of EPS
				risperidone experienced Parkinsonian symptoms, the incidence of EPS adverse events was significantly greater in the haloperidol group, compared to either of the atypical antipsychotics (P<0.05). A larger percentage of patients in each group required low-dose anticholinergics to control their EPS: 67% with haloperidol, 56% with olanzapine, and

Study and Drug Regimen	Study Design and Demographics	Sample Size and Study Duration	End Points	Results
				53% with risperidone. Significant weight gain from baseline was noted in all treatment groups: 15.7 lbs with olanzapine, 10.9 lbs with risperidone, and 7.8 lbs with haloperidol (P<0.001). The difference in weight gain was statistically significant among groups (P=0.039). Compared to the other treatment groups, patients receiving olanzapine experienced a statistically significant glucose level elevation (P=0.008), although the change from baseline did not reach statistical significance (P=0.06). Haloperidol-treated patients experienced a statistically significant QTc elevation compared to baseline (P=0.031); none of the other treatment
				groups experienced significant ECG changes from baseline.

Diabetes				
Baker et al ²⁴³ Atypical antipsychotics (olanzapine, risperidone, quetiapine, clozapine, ziprasidone, aripiprazole) or haloperidol	Data relating to diabetes-related adverse events (DRAEs) was extracted from the FDA Adverse Event Reporting System (AERS), evaluated for patients under 18 years of age, and for patients over 65 years of age	N=8,032 cases of DRAEs Duration of therapy not reported	Primary: Cases of DRAEs across age groups Secondary: Not reported	Primary: A total of 258 cases of DRAEs were identified for children and adolescents receiving atypical antipsychotics or haloperidol. Among the study drugs, olanzapine and risperidone were associated with the highest incidence of DRAEs (82 and 56 cases, respectively). Of the DRAEs identified, hyperglycemia was the most frequently reported event (61 cases) in this age group, followed by diabetes (58 cases), and increased blood glucose (37 cases). A total of 5,764 cases of DRAEs were identified for adults, aged 18 to 65 years, who received either an atypical antipsychotic or haloperidol. Olanzapine and clozapine were associated with the highest incidence of DRAEs (2,500 and 1,115 cases, respectively), followed by risperidone. Of the DRAEs, diabetes (1,825 cases) and hyperglycemia (955 cases) were the most frequently reported events in this age group. A total of 529 cases of DRAEs were identified for patients over the age of 65, who received either an atypical antipsychotic or haloperidol. Olanzapine and risperidone were associated with the highest frequency of DRAEs. Of the DRAEs, diabetes (176 cases), followed by hyperglycemia (122 cases) and increased blood glucose (116 cases) were the most frequently reported event in this age group. Across all age groups, the following reporting ratios for diabetes were found with the evaluated atypical antipsychotics: olanzapine (9.6; 95%CI, 9.2 to 10.0; 1306 cases), risperidone (3.8; 95%CI, 3.5 to 4.1; 447 cases), quetiapine (3.5; 95%CI, 3.2 to 3.9; 283 cases), clozapine (3.1; 95%CI, 2.9 to 3.3; 464 cases), ziprasidone (2.4; 95%CI, 2 to 2.9; 74 cases), aripiprazole (2.4; 95%CI, 1.9 to 2.9; 71 cases).

				Obese or overweight patients had a 14% lower mean HDL cholesterol concentration compared to lean children (P<0.05). Obese or overweight patients were also more likely than lean patients to have higher insulin and triglyceride levels (P<0.05). The odds of having at least one laboratory metabolic abnormality was approximately 12 times greater in the obese/overweight group (P<0.0001). The odds of meeting at least one metabolic syndrome criteria was seven times higher among obese/overweight patients (P=0.0002). However, the prevalence of metabolic syndrome was low in both groups. Secondary: Not reported
Maayan et al ²⁴⁶ Risperidone 0.25 mg to 4.0 mg daily	NAT Children and adolescents between the ages of 11 and 17 years diagnosed with psychotic or mood disorders, initiated on risperidone therapy in the 4 weeks prior to study onset	N=8 8 weeks	Primary: Weight gain, BMI, hip and waist circumference, waist- to-height ratio, waist- to-hip ratio, leptin, glucose, insulin, triglycerides, total cholesterol, HDL, LDL, HbA _{1c} , and cortisol levels Secondary: Not reported	Primary: At eight weeks, patients gained an average of 4.16 kg from baseline (P=0.03), with 62.5% of patients (6/8) experiencing a clinically significant weight gain, defined as a gain of more than 7% of baseline body weight. An increase in BMI from baseline was also statistically significant among patients taking risperidone for 8 weeks (P=0.03). At eight weeks, patients were observed to have larger waist circumference and hip circumference from baseline (P=0.02 and P=0.01, respectively). The waist-to-height ratio was also increased from 0.47 to 0.50 during the eight week treatment course (<i>P</i> =0.01). Risperidone nine week treatment was not associated with significant changes in waist-to-hip ratio, leptin, glucose, insulin, triglycerides, total

				baseline of 0.70 (<i>P</i> =0.40). After a median of 10.8 weeks, olanzapine-treated patients experienced a statistically significant increase in plasma glucose level (3.14 mg/dl; 95%CI, 0.69 to 5.59; <i>P</i> =0.02). Statistically significant changes in plasma glucose were not observed in association with aripiprazole, quetiapine, and risperidone (<i>P</i> >0.05). After a median of 10.8 weeks, olanzapine-treated patients experienced statistically significant increases in plasma insulin level (2.71 mIU/ml mg/dl; 95%CI, 0.42 to 5.00; <i>P</i> =0.02) and HOMA-IR (0.62; 95%CI, 0.07 to 1.17; <i>P</i> =0.03). Statistically significant changes in plasma insulin level and HOMA-IR were not observed in association with aripiprazole, quetiapine, and risperidone (<i>P</i> >0.05). After a median of 10.8 weeks, statistically significant change in the ratio of triglycerides to HDL cholesterol was observed in association with quetiapine (1.22 mg/dl; <i>P</i> =0.004), olanzapine (0.59 mg/dl; <i>P</i> =0.002), and risperidone (0.20 mg/dl; <i>P</i> =0.05). The ratio of triglycerides to HDL cholesterol decreased in the aripiprazole and untreated control groups (<i>P</i> >0.05). Olanzapine was associated with the greatest increase in total cholesterol from baseline (15.58 mg/dl; <i>P</i> <0.001). Patients receiving quetiapine also experienced a significant increase in total cholesterol levels (9.05 mg/dl; <i>P</i> <0.46). The other groups did not exhibit significant changes from baseline in total cholesterol level (<i>P</i> >0.05). Olanzapine was associated with the greatest increase in LDL cholesterol from baseline (11.54 mg/dl; <i>P</i> =0.004). Patients receiving aripiprazole experienced a marginally significant increase in LDL cholesterol levels (3.75 mg/dl; <i>P</i> =0.05). The other groups did not exhibit significant changes from baseline in LDL cholesterol level (<i>P</i> >0.05).

olanzapine of varying doses vs quetiapine of varying doses	treatment naïve or taking the study antipsychotic for <30 days		cholesterol, HDL cholesterol, triglycerides, and HbA1c, risk for adverse health outcome (defined as at least 1 of the following:1) ≥85 th BMI percentile plus presence of at least 1 negative weight- related clinical outcome, or 2) ≥95 th BMI percentile) Secondary: Not reported	compared to patients in the quetiapine group (<i>P</i> =0.001). There was no statistically significant difference in BMI z scores between risperidone and either olanzapine (<i>P</i> =0.09) or quetiapine (<i>P</i> =0.49). At six months, there was a statistically significant weight gain in patients receiving olanzapine (11.1 kg; <i>P</i> <0.01) or risperidone (5 kg; <i>P</i> =0.01), but not in patients receiving quetiapine (2.5 kg; <i>P</i> >0.05). At six months, there was a statistically significant increase in total cholesterol in patients receiving olanzapine (<i>P</i> =0.047) or quetiapine (<i>P</i> =0.016), but not in patients receiving risperidone (<i>P</i> =0.813). At six months, quetiapine therapy was associated with a statistically significant decrease in free thyroxin level from baseline (<i>P</i> =0.011). The reduction in free thyroxin levels observed in association with quetiapine was significantly greater than that seen with risperidone (<i>P</i> <0.001). At six months, olanzapine group exhibited a greater increase in systolic blood pressure from baseline compared to the risperidone group (7.4 mm Hg vs 1.3 mm Hg; P=0.011). None of the three studied antipsychotics had a significant impact on plasma glucose, LDL cholesterol, HDL cholesterol, triglycerides, and HbA1c within the evaluated time period. At six months, the number of patients at risk for adverse health outcome increased from 16.7% to 37.9% (<i>P</i> =0.001). This increase was significant only in the olanzapine group (<i>P</i> =0.012). The risk of adverse health outcome was significantly greater in patients receiving olanzapine than those using quetiapine (<i>P</i> =0.022) and in patients receiving olanzapine compared to those in the risperidone group (<i>P</i> =0.016).

Moreno et al ²⁵² Atypical antipsychotics (olanzapine, risperidone, quetiapine)	NAT Children and adolescents naïve to antipsychotics or with a maximum exposure of 30 days; patients were divided into the following 3 diagnosis groups: bipolar, other psychotic disorder, and nonpsychotic disorder	N=90 3 months	Primary: Changes in weight, BMI, cholesterol, triglycerides, plasma glucose, TSH, T4 Secondary: Not reported	(P=0.008) and in overall risk factors for metabolic syndrome (<i>P</i> =0.013). Over the course of treatment, risperidone therapy was not associated with a statistically significant change in risk factors for diabetes or metabolic syndrome. Compared to risperidone therapy, olanzapine was associated with a statistically significant increase in mean systolic blood pressure (-3.2 mm Hg vs 5.4 mm Hg; <i>P</i> =0.044). In contrast, there was no statistically significant difference between the groups in the change in diastolic blood pressure from baseline. Secondary: Not reported Primary: Antipsychotic therapy was associated with a statistically significant 5.5 kg weight gain, assessed at three months of study initiation, in all patients, regardless of the diagnosis (P<0.001). There was no statistically significant difference in weight gain among the three diagnostic groups (<i>P</i> =0.06). Significant weight gain was found in 71.1% of patients after 3 months of therapy. Antipsychotic therapy was associated with a statistically significant increase in BMI z-scores from baseline in all three treatment groups (<i>P</i> <0.001). A statistically significant increase in LDL-cholesterol from baseline was only seen in patients with bipolar disorder (<i>P</i> =0.02). In other diagnostic groups the change was not statistically significant. Total cholesterol increased significantly in patients with bipolar and psychotic disorders (<i>P</i> <0.05). HDL-cholesterol and triglycerides did not change significantly in any of

	mental health disorder Note: none of the paliperidone studies met inclusion criteria and were hence excluded from MA		Secondary: Not reported	therapy was likewise associated with a statistically significant prolactin elevation compared to placebo (OR, 30.52; P<0.00001). In contrast, aripiprazole therapy was associated with a significantly greater decrease in prolactin levels after treatment compared to placebo (-5.03 ng/ml; 95% CI, -7.80 to -2.26). Quetiapine was not associated with a significant change in prolactin levels (<i>P</i> value not reported)/ Risperidone-treated children had significantly greater odds of experiencing EPS (EPS) compared to placebo-treated patients (OR, 3.35; <i>P</i> <0.00001). Aripiprazole therapy was also associated with a statistically significant increase in the odds of EPS compared to placebo (OR, 3.70; <i>P</i> <0.00001). Risperidone was associated with a higher risk of requiring anti-cholinergic therapy for the treatment of EPS compared to olanzapine, though the difference did not reach statistical significant (<i>P</i> value not reported). Olanzapine and clozapine were associated with the greatest increases in cholesterol and triglycerides compared to placebo. The odds of high triglycerides after receiving olanzapine were higher compared to placebo, with an OR of 5.13. Cholesterol increased by a mean of 3.67 mg/dl (<i>P</i> =0.001) from baseline. Risperidone was not associated with significant changes in cholesterol, triglycerides, or glucose plasma levels compared to baseline. Quetiapine was associated with a significant increase in triglycerides levels compared to placebo (30 vs -14 mg/dl; <i>P</i> =0.003). Aripiprazole was not associated with significant changes in cholesterol, triglycerides, blood pressure or blood glucose compared to placebo (<i>P</i> value not reported). Olanzapine, aripiprazole, ziprasidone and quetiapine were not associated with significant changes in QTc interval from baseline. Olanzapine was associated with a statistically significant increase in systolic blood pressure compared to placebo (3.61 vs -2.28 mmHg; <i>P</i> =0.001). Quetiapine was also associated with significantly higher blood

At six months, patients exhibited statistically significant increases in weight from baseline (37.50 vs 31.98; <i>P</i> =0.002). There was no significant association between weight gain and changes in liver function tests (<i>P</i> value not reported). Secondary: Not reported
Usage and Safety				Not reported
Harrison-Woolrych et al ²⁶⁶ Atypical antipsychotics (clozapine, olanzapine, risperidone, quetiapine)	I, O, PRO Children and adolescents, aged 2 to 15 years, who were prescribed an atypical antipsychotic, identified through a post-marketing Prescription Event Monitoring system in Australia	N=420 641.2 patient-years	Primary: Usage, safety Secondary: Not reported	Primary: During the study period, 93% of patients included in the study received a prescription for risperidone, followed by 8, 2 and 0.2% of patients with a prescription for quetiapine, olanzapine, and clozapine, respectively. Total exposure to atypical antipsychotics was 7694 patient-months, with the majority of exposure (94%) being to risperidone. The most common indications for prescribing an antipsychotic were disruptive disorders (conduct disorder, ADHD) reported in 43% of patients, pervasive developmental disorders (34%), and cognitive impairment (17%). Aggression was the most common target symptom among pediatric patients treated by an antipsychotic, reported in 43% of the study sample. Other common target symptoms for antipsychotic therapy included behavioral difficulties (26%), anxiety (17%), hyperactivity (10%) and mood disturbances (9%). Mood disturbances were identified as a target symptom in 3% of pediatric patients prescribed

Generic	Population and Precaution						
Name	Elderly/	Renal	Hepatic	Pregnancy	Excreted in		
	Children mania in pediatric patients 10 years of age and older. Safety and effectiveness in pediatric patients for other uses have not been established.	Dysfunction	Dysfunction	Category	Breast Milk		
Brexpiprazole	Safety and efficacy in elderly patients have not been established. Safety and effectiveness in pediatric patients have not been established.	For patients with moderate, severe, or endstage renal impairment (creatinine clearance <60 mL/minute), the maximum recommended dosage is 2 mg once daily for patients with MDD and 3 mg once daily for patients with schizophrenia.	For patients with moderate to severe hepatic impairment (Child-Pugh score ≥7), the maximum recommended dosage is 2 mg once daily for patients with MDD and 3 mg once daily for patients with schizophrenia.	Not studied; increased risk for extra- pyramidal symptoms in neonates if mother is exposed during the third trimester.	Unknown; women receiving brexippra- zole should not breastfeed.		
Clozapine	Dose selection for an elderly patient should be cautious, reflecting the greater frequency of decreased hepatic, renal, or cardiac function, and of concomitant disease or other drug therapy. Safety and effectiveness in pediatric patients have not been established.	It may be necessary to reduce the dose in patients with significant renal impairment	It may be necessary to reduce the dose in patients with significant hepatic impairment.	В	Unknown; women receiving clozapine should not breastfeed.		
lloperidone	Clinical studies did not include sufficient numbers of patients aged 65 and over to determine whether or not they respond differently than younger patients. Safety and effectiveness in pediatric patients have not been established.	Renal impairment (creatinine clearance <30 mL/min) had minimal effect on maximum plasma concentrations of iloperidone and its metabolites; No dose	Use caution in moderate hepatic impairment; not recommended for patients with severe hepatic impairment.	С	Unknown; women receiving iloperidone should not breastfeed.		

Generic		Population :	and Precaution

		are required.			
Lurasidone	No dosage adjustment is recommended for elderly patients. The safety and effectiveness in pediatric patients have not been established.	Dosage adjustment is recommended in patients with moderate/ severe renal impairment (dose should not exceed 80 mg daily).	Dosage adjustment is recommended in patients with moderate/ severe hepatic impairment (dose should not exceed 80 or 40 mg daily based on impairment).	В	Unknown; women receiving lurasidone should not breastfeed.
Olanzapine	Consider a lower starting dose for any elderly patient if factors are present that might decrease pharmacokinetic clearance or increase the pharmacodynamic response. The safety and effectiveness in pediatric patients with schizophrenia or manic/mixed bipolar I disorder less than 13 years of age have not been established. Safety and effectiveness in pediatric patients with other conditions have not been established.	Dosage adjustment based upon the degree of renal function impairment is not required.	Exercise caution in patients with signs and symptoms of hepatic function impairment, preexisting conditions associated with limited hepatic functional reserve, or being treated with potentially hepatotoxic drugs.	С	Excreted into breast milk; Women receiving olanzapine should not breastfeed.
Paliperidone	Because elderly patients may have diminished renal function, dose adjustments may be required according to their renal function status. In general, the recommended dosing for elderly patients with healthy renal	Dose according to the patient's renal function. For mild renal impairment (creatinine clearance 50 to <80 mL/ minute), the recommended initial dosage is 3 mg daily;	For patients with mild to moderate hepatic impairment no dose adjustment is recommend- ed. Not studied in patients with severe hepatic	C.	Excreted into breast milk; The known benefits of breast-feeding should be weighed against the known risks of infant exposure.

a Percent not specified.

#Narrow-angle glaucoma.

⁻ Event not reported or incidence <1%.

^{*}Includes orthostatic. †Includes petit and grand mal seizures.

[‡]Exfoliative dermatitis included.

[§]Contact dermatitis included.

Fungal dermatitis.

¶Gained at least 7% body weight.

Contraindications

Table 13. Contraindications-Single Entity Products 1-14

Contraindication(s)	Aripiprazole	Asenapine	Brexpiprazole	Clozapine	lloperidone	Lurasidone	Olanzapine	Paliperidone	Quetiapine	Risperidone	Ziprasidone
Concurrent use with dofetilide, sotalol, quinidine, Class 1a and III antiarrhythmics, mesoridazine, thioridazine, chlorpromazine, droperidol, pimozide, sparfloxacin, gatifloxacin, moxifloxacin, halofantrine, mefloquine, pentamidine, arsenic trioxide, levomethadyl acetate, dolasetron mesylate probucol, or tacrolimus	-	-	-	ı	-	ı	-	ı	ı	-	а
Concurrent use with other agents that have demonstrated QT prolongation as a pharmacodynamic effect and have this effect described in the full prescribing information as a contraindication or as a boxed or bolded warning	-	-	-	-	-	-	-	-	ı	-	а
Concurrent use with other agents with well-known potential to cause agranulocytosis or suppress bone marrow function	-	-	-	а	-	-	-	-	ı	-	-
Concurrent use with strong CYP3A4 inducers	-	-	-	-	-	а	-	-	-	-	-
Concurrent use with strong CYP3A4 inhibitors	_	-	-	-	-	а	-	-	-	-	-
History of clozapine-induced agranulocytosis or severe granulocytopenia	-	-	-	а	-	-	-	_	-	-	-
History of QT prolongation including congenital long QT syndrome	-	-	-	-	-	-	-	-	-	-	а
Hypersensitivity to the drug or its ingredients	а	а	а	а	а	а	а	а	а	а	а
Recent acute myocardial infarction	-	-	-	-	-	-	-	-	-	-	а
Uncompensated heart failure	-	-	-	-	-	-	-	-	-	-	а

Boxed Warnings

Black Box Warning for Antipsychotics¹⁻¹⁴

WARNING

Increased mortality in elderly patients with dementia-related psychosis: Elderly patients with dementia-related psychosis treated with antipsychotic drugs are at an increased risk of death. Analyses of 17 placebo-controlled trials (modal duration of 10 weeks), largely in patients taking atypical antipsychotic drugs, revealed a risk of death in the drug-treated patients of between 1.6 to 1.7 times that seen in placebo-treated patients. Over the course of a typical 10-week controlled trial, the rate of death in drug-treated patients was about 4.5%, compared to a rate of about 2.6% in the placebo group. Although the causes of death were varied, most of the deaths appeared to be either cardiovascular (e.g., heart failure, sudden death) or infectious (e.g., pneumonia) in nature. Observational studies suggest that, similar to atypical antipsychotic drugs, treatment with conventional antipsychotic drugs may increase mortality. The extent to which the findings of increased mortality in observational studies may be attributed to the antipsychotic drug as opposed to some characteristic(s) of the patients is not clear.

Black Box Warning for Aripiprazole¹

WARNING

Suicidality and antidepressant drugs: Antidepressants increased the risk of suicidal thinking and behavior (suicidality) in children, adolescents, and young adults in short-term studies of major depressive disorder and other psychiatric disorders. Anyone considering the use of adjunctive aripiprazole or any other antidepressant in a child, adolescent, or young adult must balance this risk with the clinical need. Short-term studies did not show an increase in the risk of suicidality with antidepressants compared to placebo in adults older than 24 years of age; there was a reduction in risk with antidepressants compared to placebo in adults 65 years of age and older. Depression and certain other psychiatric disorders are themselves associated with increases in the risk of suicide. Patients of all ages who are started on antidepressant therapy should be monitored appropriately and observed closely for clinical worsening, suicidality, or unusual changes in behavior. Families and caregivers should be advised of the need for close observation and communication with the prescriber. Aripiprazole is not approved for use in children with depression.

Black Box Warning for Brexpiprazole³

WARNING

Suicidality thoughts and behaviors: Antidepressants increased the risk of suicidal thoughts and behaviors in patients aged 24 years and younger in short-term studies. Monitor closely for clinical worsening and for emergence of suicidal thoughts and behaviors. The safety and efficacy of **brexpiprazole** have not been established in pediatric patients.

Black Box Warnings for Clozapine⁴⁻⁶

WARNING

Agranulocytosis: Because of a significant risk of agranulocytosis, a potentially life-threatening adverse reaction, reserve clozapine for use in the treatment of severely ill patients with schizophrenia who fail to show an acceptable response to adequate courses of standard antipsychotic drug treatment or for use in reducing the risk of recurrent suicidal behavior in patients with schizophrenia or schizoaffective disorder who are judged to be at risk of reexperiencing suicidal behavior.

Patients being treated with clozapine must have a baseline white blood cell count and absolute neutrophil count before initiation of treatment, as well as regular white blood cell count counts and absolute neutrophil counts during treatment and for at least four weeks after discontinuation of treatment.

Clozapine is available only through a distribution system that ensures monitoring of white blood cell count

WARNING

counts and absolute neutrophil counts according to the following schedule prior to delivery of the next supply of medication.

Seizures: Seizures have been associated with the use of clozapine. Dose appears to be an important predictor of seizure, with a greater likelihood at higher clozapine doses. Use caution when administering clozapine to patients who have a history of seizures or other predisposing factors. Advise patients not to engage in any activity in which sudden loss of consciousness could cause serious risk to themselves or others.

Myocarditis: Analyses of postmarketing safety databases suggest that clozapine is associated with an increased risk of fatal myocarditis, especially during, but not limited to, the first month of therapy. In patients in whom myocarditis is suspected, promptly discontinue clozapine treatment.

Other adverse cardiovascular and respiratory reactions: Orthostatic hypotension, with or without syncope, can occur with clozapine treatment. Rarely, collapse can be profound and be accompanied by respiratory and/or cardiac arrest. Orthostatic hypotension is more likely to occur during initial titration in association with rapid dose escalation. In patients who have had even a brief interval off clozapine (two or more days since the last dose), start treatment with 12.5 mg once or twice daily.

Because collapse, respiratory arrest, and cardiac arrest during initial treatment have occurred in patients who were being administered benzodiazepines or other psychotropic drugs, caution is advised when clozapine is initiated in patients taking a benzodiazepine or any other psychotropic drug. (See group monograph.) Antipsychotic Agents.

Black Box Warning for Lurasidone⁸

WARNING

Antidepressants increased the risk of suicidal thoughts and behavior in children, adolescents, and young adults in short-term studies. These studies did not show an increase in the risk of suicidal thoughts and behavior with antidepressant use in patients over age 24; however, there was a reduction in risk with antidepressant use in patients aged 65 and older. In patients of all ages who are started on antidepressant therapy, monitor closely for worsening, and for emergence of suicidal thoughts and behaviors. Advise families and caregivers of the need for close observation and communication with the prescriber.

Black Box Warning for Quetiapine and Quetiapine Fumarate 11,12

WARNING

Suicidality and antidepressant drugs: Antidepressants increased the risk of suicidal thinking and behavior (suicidality) in children, adolescents, and young adults in short-term studies of major depressive disorder and other psychiatric disorders. Anyone considering the use of Seroquel XR® or any other antidepressant in a child, adolescent, or young adult must balance this risk with the clinical need. Short-term studies did not show an increase in the risk of suicidality with antidepressants compared to placebo in adults older than 24 years of age; there was a reduction in risk with antidepressants compared to placebo in adults 65 years of age and older. Depression and certain other psychiatric disorders are themselves associated with increases in the risk of suicide. Patients of all ages who are started on antidepressant therapy should be monitored appropriately and observed closely for clinical worsening, suicidality, or unusual changes in behavior. Families and caregivers should be advised of the need for close observation and communication with the prescriber. Seroquel XR® is not approved for use in pediatric patients.

Frequency of Monitoring Based on Stage of Clozapine Therapy or Results from White Blood Cell Count and Absolute Neutrophil Count Monitoring Tests⁴⁻⁶

Situation	Hematological Values for Monitoring	Frequency of White Blood Cell and Absolute Neutrophil Count Monitoring
Initiation of therapy	WBC ≥3,500/mm ³ ANC ≥2,000/mm ³ Do not initiate in patients with history of myeloproliferative disorder or clozapine-induced agranulocytosis or granulocytopenia	Weekly for 6 months
6 to 12 months of therapy	All results for WBC ≥3,500/mm ³ and ANC ≥2,000/mm ³	Every 2 weeks for 6 months
12 months of therapy	All results for WBC ≥3,500/mm ³ and ANC ≥2,000/mm ³	Every 4 weeks ad infinitum
Immature forms present	N/A	Repeat WBC and ANC
Discontinuation of therapy	N/A	Weekly for at least 4 weeks from day of discontinuation or until WBC ≥3,500/mm³ and ANC >2,000/mm³
Substantial drop in WBC or ANC	Single drop or cumulative drop within 3 weeks of WBC ≥3,000/mm³ and ANC ≥1,500/mm³	 Repeat WBC and ANC If repeat values are 3,000/mm³ ≤ WBC ≤3,500/mm³ and ANC >2,000/mm³, then monitor twice weekly
Mild leukopenia Mild granulocytopenia	3,500/mm³ > WBC ≥3,000/mm³ and/or 2,000/mm³ > ANC ≥1,500/mm³	Twice weekly until WBC >3,500/mm ³ and ANC >2,000/mm ³ , then return to previous monitoring frequency
Moderate leukopenia Moderate granulocytopenia	3,000/mm³ > WBC ≥2,000/mm³ and/or 1,500/mm³ > ANC ≥1,000/mm³	 Interrupt therapy Daily until WBC >3,000/mm³ and ANC >1,500/mm³ Twice weekly until WBC >3,500/mm³ and ANC >2,000/mm³ May rechallenge when WBC >3,500/mm³ and ANC >2,000/mm³ If rechallenged, monitor weekly for 1 year before returning to the usual monitoring schedule of every 2 weeks for 6 months and then every 4 weeks ad infinitum
Severe leukopenia Severe granulocytopenia	WBC <2,000/mm ³ and/or ANC <1,000/mm ³	Discontinue treatment and do not rechallenge patient Monitor until normal and for at least 4 weeks from day of discontinuation as follows: Daily until WBC >3,000/mm³ and ANC >1,500/mm³ Twice weekly until WBC >3,500/mm³ and ANC >2,000/mm³ Weekly after WBC

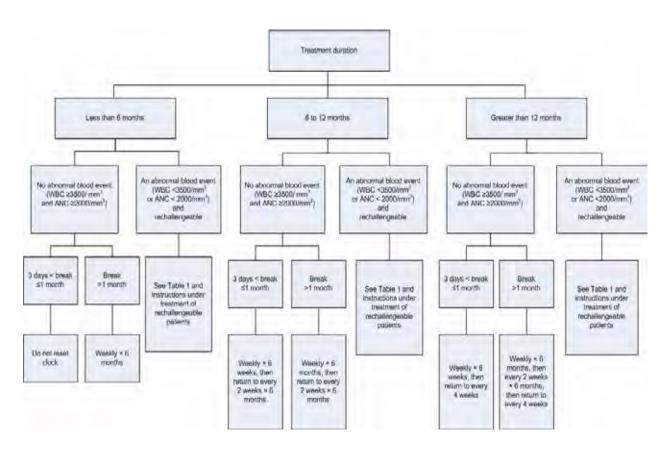

Situation	Hematological Values for Monitoring	Frequency of White Blood Cell and Absolute Neutrophil Count Monitoring
Agranulocytosis	ANC ≤500/mm ³	1. Discontinue treatment and do not rechallenge patient 2. Monitor until normal and for at least 4 weeks from day of discontinuation as follows: Daily until WBC 3,000/mm³ and ANC 1,500/mm³ Twice weekly until WBC 3,500/mm³ and ANC 2,000/mm³ Weekly after WBC 3,500/mm³

ANC=absolute neutrophil count, N/A=not applicable, WBC=white blood cell count

Resuming Monitoring Frequency for Clozapine Treatment after an Interruption in Therapy $^{\!\!\!\!^{4-6}}$

Drug Interactions

Table 15. Significant Drug-Drug Interactions 1-14

Table 10. Oigili	icant Drug-Drug Inte	
Drug(s)	Medication or Disease	Mechanism
Aripiprazole, iloperidone, quetiapine, risperidone	Azole antifungals	Inhibition of metabolism through CYP3A4 by azole antifungals may result in increased concentrations. When the azole antifungal is discontinued, adjust the dose.
Aripiprazole, quetiapine, risperidone	Carbamazepine	Induction of metabolism through CYP3A4 by carbamazepine may result in decreased concentrations, decreasing the pharmacologic effects. When carbamazepine is discontinued, adjust the dose.
Clozapine, iloperidone, risperidone	Serotonin- reuptake inhibitors	Serum levels may be elevated, resulting in increased pharmacologic and toxic effects. Monitor serum levels, observe clinical response and adjust the dose as needed.
Aripiprazole	Quinidine	Inhibition of aripiprazole metabolism through CYP2D6 by quinidine may result in increased aripiprazole concentrations, increasing the pharmacologic and adverse effects. When quinidine is discontinued, adjust the dose of aripiprazole.
Brexpiprazole	Strong CYP2D6 and CYP3A4 inhibitors	Increased expose to brexpiprazole. Reduce the dose of brexpiprazole by one-half with concurrent use of a strong CYP2D6 or CYP3A4 inhibitor. No dose adjustment is required for concurrent use of a strong CYP2D6 inhibitor in patients treated for major depressive disorder
Brexpiprazole	CYP3A4 inducers AND CYP2D6 inhibitor	Increased exposure to brexpiprazole. Reduce the dose to one- quarter the normal dose if the patient is concurrently using any strong/moderate CYP3A4 inhibitor and a strong/moderate CYP2D6 inhibitor.
Brexpiprazole	CYP3A4 inducers	Decreased exposure of brexpiprazole. Double the usual dose with concurrent use of a CYP3A4 inhibitor. Additional doseadjustment may be required.
Clozapine	Barbiturates	Induction of clozapine metabolism by barbiturates may result in decreased clozapine concentrations, decreasing the pharmacologic effects of clozapine. Observe the patient for clozapine toxicity when phenobarbital is stopped.
Clozapine	Benzodiazepines	The pharmacologic or toxic effects of certain benzodiazepines may be increased with concomitant administration. Consider monitoring vital signs and observing patients for excessive adverse reactions.
Clozapine	Quinolones	Clozapine plasma concentrations may be elevated due to inhibition of metabolism (CYP1A2) by certain quinolone antibiotics, increasing the risk of adverse reactions. Observe the clinical response of the patient and adjust the dose of clozapine as needed.
Clozapine	Ritonavir	Inhibition of clozapine metabolism through CYP2D6 by ritonavir may result in increased clozapine concentrations, increasing risk of toxicity. Coadministration is contraindicated.
lloperidone	Agents that prolong the QT interval	Concomitant administration may increase the risk of life- threatening cardiac arrhythmias, torsades de pointes or QT prolongation. Coadministration is contraindicated.
Lurasidone	Strong CYP3A4	Concomitant administration is contraindicated. Coadministration

Drug(s)	Interacting Medication or Disease	Mechanism
	inhibitors (i.e.	has resulted in significant increases in lurasidone Cmax and
	ketoconazole)	AUC, via inhibition of CYP3A4-mediated lurasidone metabolism.
Lurasidone	Strong CYP3A4	Concomitant administration is contraindicated. Coadministration
	inducers (i.e.	has resulted in significant increases in lurasidone Cmax and
	rifampin)	AUC, via induction of CYP3A4-mediated lurasidone metabolism.
Lurasidone	Moderate	Concomitant use of diltiazem and lurasidone has resulted in
	CYP3A4 inhibitor	significant increases in lurasidone Cmax and AUC, via inhibition
	(diltiazem)	of CYP3A4-mediated lurasidone metabolism. Therefore, the lurasidone dose should not exceed 40 mg/day when
		coadministered with diltiazem.
Lurasidone	Lithium	Concomitant use of lithium and lurasidone has resulted in
		increases in lurasidone Cmax and AUC. However, no lurasidone
		dose adjustments are required with concomitant use.
Olanzapine	Protease inhibitors	Increased metabolism of olanzapine through CYP1A2 by
		protease inhibitors may result in decreased olanzapine
		concentrations, decreasing the therapeutic effects. Adjust the
		dose of olanzapine as needed.
Quetiapine	Hydantoins	Increased metabolism of quetiapine through CYP3A4 by
		hydantoins may result in decreased quetiapine concentrations,
Overtioning	Malanaia asid	decreasing pharmacologic effects.
Quetiapine	Valproic acid	Quetiapine plasma concentrations may be elevated due to
		inhibition of metabolism (CYP3A4) by valproic acid, increasing the pharmacologic and adverse effects. Closely monitor patients
		and be prepared to change the quetiapine dose as needed.
Ziprasidone	Antiarrhythmics	Concomitant administration may increase the risk of life-
2.0.000000	, and anny annies	threatening cardiac arrhythmias, torsades de pointes or QT
		prolongation. Coadministration is contraindicated.
Ziprasidone	Cisapride	Concomitant administration may increase the risk of life-
		threatening cardiac arrhythmias, torsades de pointes or QT
		prolongation. Coadministration is contraindicated.
Ziprasidone	Dofetilide	Concomitant administration may increase the risk of life-
		threatening cardiac arrhythmias, torsades de pointes or QT
	D	prolongation. Coadministration is contraindicated.
Ziprasidone	Dolasetron	Concomitant administration may increase the risk of life-
		threatening cardiac arrhythmias, torsades de pointes or QT prolongation. Coadministration is contraindicated.
Ziprasidone	Droperidol	Concomitant administration may increase the risk of life-
Ziprasidone	Diopendoi	threatening cardiac arrhythmias, torsades de pointes or QT
		prolongation. Coadministration is contraindicated.
Ziprasidone	Halofantrine	Concomitant administration may increase the risk of life-
		threatening cardiac arrhythmias, torsades de pointes or QT
		prolongation. Coadministration is contraindicated.
Ziprasidone	Mefloquine	Concomitant administration may increase the risk of life-
		threatening cardiac arrhythmias, torsades de pointes or QT
	1	prolongation. Coadministration is contraindicated.
Ziprasidone	Pentamidine	Concomitant administration may increase the risk of life-
		threatening cardiac arrhythmias, torsades de pointes or QT
Zinrasidana	Phenothiazines	prolongation. Coadministration is contraindicated.
Ziprasidone	FITEHOUHIAZITIES	Concomitant administration may increase the risk of life- threatening cardiac arrhythmias, torsades de pointes or QT
		threatering cardiac arrivininas, torsades de polítics of Q1

Drug(s)	Interacting Medication or Disease	Mechanism
		prolongation. Coadministration is contraindicated.
Ziprasidone	Pimozide	Concomitant administration may increase the risk of life- threatening cardiac arrhythmias, torsades de pointes or QT prolongation. Coadministration is contraindicated.
Ziprasidone	Quinolones	Concomitant administration may increase the risk of life- threatening cardiac arrhythmias, torsades de pointes or QT prolongation. Coadministration is contraindicated.
Ziprasidone	Tacrolimus	Concomitant administration may increase the risk of life- threatening cardiac arrhythmias, torsades de pointes or QT prolongation. Coadministration is contraindicated.

Clinical Guidelines

Table 14. Clinical Guidelines in Adults

Guideline	Recommendations
Anxiety Disorder	
National Collaborating	High-intensity psychological interventions
Centre for Mental Health,	If a patient with generalized anxiety disorder (GAD) chooses a high-
National Institute for	intensity psychological intervention, cognitive behavioral therapy
Health and Clinical	(CBT) or applied relaxation may be offered.
Excellence:	
Generalised Anxiety	Pharmacotherapy
Disorder and Panic	If pharmacotherapy is chosen, selective serotonin reuptake inhibitors
Disorder (with or without	(SSRIs) are preferred. Sertraline is the most cost-effective treatment
agoraphobia) in Adults:	option and may be used first-line.
Management in Primary	If sertraline is ineffective, either an alternative SSRI or a serotonin-

IM=intramuscular, PO=by mouth
*Please refer to individual package insert for titration of dose information.
†Initial dose titration is not required.

[‡]There is no clinical data supporting maintenance dosing. §No dosing data is available for children who weighed less than 15 kg.

[¶]Administration for more than three consecutive days has not been studied.
**In combination with fluoxetine 20 mg (adults and children)

Guideline	Recommendations
Secondary and	norepinephrine reuptake inhibitor (SNRI) may be offered.
Community Care (update) (2011) ²⁹¹	 If a patient cannot tolerate either a SSRI or a SNRI, pregabalin may be tried. Benzodiazepines or antipsychotics should not be used for the treatment of GAD in primary care. Efficacy and safety should be evaluated every 2-4 weeks during the
	first 3 months of therapy and every 3 months subsequently. If a drug is effective, therapy should continue for at least one year as the risk of relapse is high.
Amoniana Davahiatria	 Complex, treatment-refractory GAD Combination of psychological and pharmacotherapy may be offered. Alternatively, combinations of antidepressants or augmentation of antidepressants with other drugs may be tried. However, the evidence for the effectiveness of combination treatments is lacking and side effects and interactions are more likely when combining and augmenting antidepressants. Combination therapy should only be initiated by practitioners with expertise in the psychological and drug treatment of complex, treatment-refractory anxiety disorders and after full discussion with the patients about the benefits and risks of therapy.
American Psychiatric Association: Practice guideline for the treatment of patients with panic disorder (2009) ²⁹²	Initial therapy The use of a selective serotonin reuptake inhibitor (SSRI), serotonin- norepinephrine reuptake inhibitor (SNRI), tricyclic antidepressant (TCA), benzodiazepine (appropriate as monotherapy only in the absence of a co-occurring mood disorder), or CBT as the initial treatment for panic disorder is strongly supported by demonstrated efficacy in numerous randomized controlled trials. There is insufficient evidence to recommend any of these pharmacological or psychosocial interventions as superior to the others, or to routinely recommend a combination of treatments over monotherapy. Considerations that guide the choice of an initial treatment modality include patient preference, the risks and benefits for the particular patient, the patient's past treatment history, the presence of co- occurring general medical and other psychiatric conditions, cost, and treatment availability. Psychosocial treatment (i.e.CBT) is recommended for patients who prefer non-pharmacological treatment and are able to commit to weekly sessions and complete between-session practices. Pharmacotherapy (SSRI or SNRI) is recommended for patients who prefer this modality or who do not have sufficient time or other resources to engage in psychosocial treatment. Adding psychosocial treatment to pharmacotherapy either from the start, or at some later point in treatment, may enhance long-term outcomes by reducing the likelihood of relapse when pharmacological treatment is stopped.
	Patients who have failed first-line therapy may either augment the current treatment by adding another agent or another modality (i.e.CBT), or add pharmacotherapy if the patient is already receiving

Guideline	Recommendations
Guideime	CBT, or they can switch to a different medication or treatment
	 real switch to a different field cation of treatment modality. If one first-line treatment (e.g., CBT, SSRI, or SNRI) has failed, adding or switching to another first-line treatment is recommended]. Adding a benzodiazepine to an antidepressant is a common augmentation strategy to target residual symptoms. After first- and second-line treatments and augmentation approaches have failed (either due to lack of efficacy or intolerance), less well-supported treatment approaches may be considered. These include monotherapy or augmentation with gabapentin or a second-generation antipsychotic or with a psychotherapeutic intervention other than CBT or panic-focused psychodynamic psychotherapy.
Bipolar Disorder	
Veterans Affairs/Department of Defense: Clinical Practice Guideline for Management of Bipolar Disorder in Adults (2010) ²⁹³	 Bipolar mania or mixed bipolar disorder Pharmacotherapy for bipolar mania or mixed episode should start with initiation or optimization of a medication that has been shown to be the most effective in treating bipolar manic episodes while minimizing the potential risks. Agents that are most likely to be beneficial for mania are the following: lithium, valproate, carbamazepine, aripiprazole, olanzapine, quetiapine, risperidone, or ziprasidone. In addition, lithium or valproate may be combined with an atypical antipsychotic. Agents most likely to be beneficial for the treatment of a mixed bipolar episode are valproate, carbamazepine, aripiprazole, olanzapine, risperidone, or ziprasidone. Agents that are unlikely to be beneficial either for bipolar mania or mixed bipolar are lamotrigine, topiramate, or gabapentin. Clozapine, haloperidol and oxcarbazepine may be considered in patients with mania or mixed episode. [I] Lithium or quetiapine may be considered in patients with mixed episode. Treatment response should be evaluated at 4 to 8 weeks after initiation of treatment, after each change in treatment, and periodically until full remission is achieved. In patients who reach full remission, assessment of symptoms should be continued periodically to monitor for relapse or recurrence. Patients who have failed monotherapy may consider switching to another monotherapy, combining a non-antipsychotic mood stabilizer (lithium or valproate) with a second generation antipsychotic. Clozapine, with its more serious side effect profile, may be combined with valproate or lithium as a treatment of severe mania or mixed episode, if it has been successful in the past or if other antipsychotics have failed.
	 Pharmacotherapy for bipolar depression Pharmacotherapy for bipolar depression should start with initiation or optimization of a medication that has been shown to be the most effective in treating bipolar depressive episodes, while minimizing the potential risks. Quetiapine, lamotrigine, or lithium monotherapy should be considered as first-line treatment for adult patients with bipolar depression. Olanzapine/fluoxetine combination should be considered for treatment of bipolar depression, but its adverse effects (weight gain,

Guideline	Recommendations
	risk of diabetes, hypertriglyceridemia) places this combination as a
	second-line treatment. Olanzapine alone may also be considered for
	bipolar depression, but adverse effects require caution.
	Agents that had been effective in treating prior episodes of
	depression should be considered.
	There is insufficient evidence to recommend for or against the use of
	valproate, carbamazepine, topiramate, risperidone, ziprasidone, or
	clozapine for BD depression.
	Aripiprazole is not recommended for monotherapy in the treatment of
	acute bipolar depression, unless there is a history of previous good
	response during depression without switch to mania or a history of
	treatment refractory depression.
	Combining lithium with lamotrigine can be considered for patients
	with bipolar depression who do not respond to monotherapy.
	· When patients do not respond to treatment options that have shown
	better efficacy, antidepressant augmentation with SSRI, SNRI,
	bupropion, and monoamine oxidase inhibitor (MAOI) can be
	considered for short-term treatment, monitoring closely for triggering
	of manic symptoms.
	Clozapine may be considered for augmentation, using caution
	regarding metabolic or other adverse effects.
	There is insufficient evidence to recommend for or against use of
	augmentation with aripiprazole, olanzapine, risperidone, haloperidol,
	oxcarbazepine, topiramate, ziprasidone, valproate, or carbamazepine
	for the treatment of bipolar depression.
	Gabapentin and the tricyclic antidepressants (TCAs) are not
	recommended for monotherapy or augmentation in the treatment of
	acute bipolar depression, unless there is a history of previous good
	response during depression without switch to mania or a history of
	treatment refractory depression.
	If there is no response within 2 to 4 weeks on an adequate dose of
	medication, therapy should be adjusted by either augmenting with
	additional agents, discontinuing switching to another effective
	medication or electroconvulsive therapy if multiple medication trials
	have been ineffective.

Assessment and	 Offer an antipsychotic regardless of whether the
Management of Bipolar	antidepressant is stopped.
Disorder in Adults,	If a person develops mania or hypomania and is not taking an
Children and	antipsychotic or mood stabilizer, offer haloperidol, olanzapine,
Adolescents, in Primary	quetiapine or risperidone.
And Secondary Care	If the first antipsychotic is poorly tolerated at any dose (including rapid
(2014) ²⁹⁴	weight gain) or ineffective at the maximum licensed dose, offer an
	alternative antipsychotic
	If an alternative antipsychotic is not sufficiently effective at the
	maximum licensed dose, consider adding lithium, and if lithium is
	ineffective or not suitable, consider valproate instead.
	If a person develops mania or hypomania and is taking an
	antidepressant in combination with a mood stabilizer, consider

Guideline	Recommendations
Guidenne	stopping the antidepressant.
	 If already taking lithium, consider adding haloperidol, olanzapine, quetiapine or risperidone.
	 If the person is already taking valproate or another mood stabilizer as prophylactic treatment, consider increasing the dose, up to the maximum level.
	Consider adding haloperidol, olanzapine, quetiapine or risperidone
	Do not offer lamotrigine to treat mania.
	Acute depressive episode in adults If a person develops moderate or severe bipolar depression and is not taking a drug to treat their bipolar disorder, offer fluoxetine combined with olanzapine, or quetiapine on its own. Olanzapine or lamotrigine monotherapy may be considered. If no response from combination olanzapine/fluoxetine or quetiapine alone, consider lamotrigine
	 If a person develops moderate or severe bipolar depression and is already taking lithium or valproate, check their plasma lithium or valproate level. If it is inadequate, increase the dose of lithium; if it is at maximum level, add either fluoxetine/olanzapine combination or quetiapine alone Patients with concurrent depressive and psychotic symptoms may be managed with olanzapine, quetiapine, or risperidone if the depressive
	illness is severe. Long-term management
	Lithium is first line for long-term therapy. Consider valproate or olanzapine if lithium is ineffective or cannot be taken.
	 Quetiapine or lamotrigine can be considered for the management of patients with chronic and recurrent depressive symptoms. Long-acting intramuscular antipsychotic injections should not be used routinely.
	Stop treatment gradually and monitor the person for signs of relapse.
The Texas Medication Algorithm Project: Texas Implementation of Medication Algorithms Procedural Manual: Bipolar Disorder Algorithms (2007) ²⁹⁵	 Treatment of hypomanic or manic episodes Stage 1 treatment options for euphoric symptoms include: lithium, valproate, aripiprazole, quetiapine, risperidone, and ziprasidone. Stage 1 treatment options for mixed symptoms include: valproate, aripiprazole, risperidone, and ziprasidone. Stage 1b, olanzapine and carbamazepine are potential alternatives to stage 1 agents.
	 Stage 2 treatment options include a combination with two of the following: lithium, valproate, olanzapine, quetiapine, risperidone, or ziprasidone (not 2 antipsychotics). Stage 3 treatment options include a different combination than that tried in Stage 2, with additional options including carbamazepine, oxcarbazepine, aripiprazole, and a typical antipsychotic. Stage 4 treatment options include clozapine or 3-drug combinations (include lithium, an anticonvulsant mood stabilizer [valproate, carbamazepine, or oxcarbazepine], plus an atypical antipsychotic).

Guideline	Recommendations
Guidellile	Treatment of depression
Annaire - Develoration	 Stage 1 recommended treatment is lamotrigine monotherapy for those patients without a recent and/or severe history of manic symptoms. Others should receive lamotrigine plus a mood stabilizer. Stage 2 treatment options include quetiapine monotherapy or the olanzapine/fluoxetine combination treatment. For Stage 3 and beyond, evidence-based medicine is limited to case series, open-label studies and expert clinical consensus. A variety of treatment options are suggested. For intolerance or unresponsiveness to agents used in a particular Stage, it is recommended to try an alternative mood stabilizer within that Stage.
American Psychiatric Association:	Treatment of acute manic or mixed episodes Adjunctive antipsychotic treatment is recommended for manic or
Practice Guideline for	mixed manic episodes with psychotic features.
the Treatment of Patients with Bipolar Disorder (2002) ^{†296}	Second generation antipsychotics are preferable over first generation antipsychotics because of their side effect profile.
	Treatment of acute depressive episodes Patients presenting with psychotic features would require adjunctive treatment with an antipsychotic medication or electroconvulsive therapy.
	Treatment of acute rapid cycling A combination regimen containing a second generation antipsychotic may also be used. Maintenance treatment for manic/depressive episode Ongoing adjunctive antipsychotic therapy should be reassessed, and slowly tapered, unless required for control of persistent psychosis or
Dementia	prophylaxis against recurrence.
American Psychiatric	Treatment of cognitive symptoms
Association: Practice Guideline for the Treatment of Patients with Alzheimer's Disease and Other Dementias (2007) ²⁹⁷	 Cholinesterase inhibitors should be offered to patients with mild to moderate Alzheimer's disease after a thorough discussion of their potential risks and benefits, and they may be helpful for patients with severe Alzheimer's disease. Cholinesterase inhibitors should be considered for patients with mild to moderate dementia associated with Parkinson's disease. Cholinesterase inhibitors can be considered for patients with dementia with Lewy bodies. Memantine, a noncompetitive N-methyl-D-aspartate (NMDA) antagonist, may provide modest benefits and has few adverse effects; thus, it may be considered. There is some evidence of its benefit in mild Alzheimer's disease and very limited evidence of its benefit in vascular dementia.
	 Treatment of psychosis and agitation Psychosis, aggression, and agitation are common in patients with dementia and may respond to similar therapies. On the basis of good evidence, antipsychotic medications are recommended for the treatment of psychosis in patients with

Cuidalina	Decemmendations
Guideline	Recommendations dementia and for the treatment of agitation.
	These medications have also been shown to provide modest
	improvement in behavioral symptoms in general.
	Evidence for a difference in efficacy and safety among antipsychotic
	medications is limited.
	 Antipsychotic medications as a group are associated with a number of severe adverse events, including increased risks for death, cerebrovascular accidents, tardive dyskinesia, neuroleptic malignant syndrome, hyperlipidemia, weight gain, diabetes mellitus, sedation, parkinsonism, and worsening of cognition. Thus, they must be used with caution and at the lowest effective dosage, after considering the risks of not treating the psychiatric symptoms. Data demonstrating benefit from benzodiazepines are modest, but benzodiazepines occasionally have a role in treating patients with prominent anxiety or on an as-needed basis for patients with infrequent episodes of agitation or for those who require sedation for a procedure. Lorazepam and oxazepam, which have no active metabolites, are preferable to agents with a longer half-life such as diazepam or clonazepam. There is minimal evidence for the efficacy of anticonvulsants, lithium, and beta-blockers for the treatment of psychosis or agitation in dementia, and these medications have significant adverse effects; therefore, they are generally not recommended except for patients for whom other treatments have failed. The antidepressant trazodone and the SSRIs are not well studied but
	may be appropriate for nonpsychotic patients with agitation.
	 Treatment of depression: Clinical consensus supports a trial of an antidepressant to treat clinically significant, persistent depressed mood. SSRIs may be preferred because they appear to be better tolerated than other antidepressants. Bupropion, venlafaxine, and mirtazapine may also be effective. Agents with substantial anticholinergic effects (e.g., amitriptyline, imipramine) should be avoided. Psychostimulants, bupropion, bromocriptine, and amantadine may be helpful for apathy. Psychostimulants are also sometimes useful in the treatment of depression in patients with significant general medical illness.
	 Treatment of sleep disturbances: If a patient requires medication for another psychiatric condition, an agent with sedating properties, given at bedtime, is preferred. For primarily sleep disturbance, medications with possible effectiveness include trazodone, zolpidem, or zaleplon, but there are few data on the efficacy of specific agents. Benzodiazepines are not recommended for other than brief use because of risks of daytime sedation, tolerance, rebound insomnia, worsening cognition, falls, disinhibition, and delirium. Diphenhydramine is not recommended because of its anticholinergic properties. Antipsychotic medications should not be used solely for the purpose

Cuidolino	Decemmendations
Guideline	Recommendations
Fating Diagraps	of treating sleep disturbances.
Eating Disorder World Federation of	Anaravia Narvasa
Societies of Biological Psychiatry: Guidelines for the Pharmacological Treatment of Eating Disorders (2011) ²⁹⁸	 Anorexia Nervosa Zinc supplementation may be used. Olanzapine may be used for weight gain. The other atypical antipsychotics have an less evidence supporting their use compared to olanzapine. Antidepressants are not associated with weight gain, but can improve depressive symptoms.
	Bulimia Nervosa Imipramine, desipramine, fluoxetine, and topiramate may be used to reduce bulimic behavior. Fluvoxamine and sertraline may reduce bulimic behavior.
	 Binge Eating Disorder Imipramine, citalopram, escitalopram, sertraline, topiramate, and sibutramine may be used to reduce binge eating behavior. Zonisamide may reduce binge eating behavior.
American Psychiatric Association: Practice Guideline for the Treatment of Patients with Eating Disorders (2012) ²⁹⁹	 Anorexia nervosa The limited empirical data on SSRIs do not suggest a role in weight gain. Atypical antipsychotics, especially olanzapine, risperidone, and quetiapine, have been studied in small case series and case studies. These agents may be useful in patients with severe, unremitting resistance to gaining weight, severe obsessional thinking, and denial that assumes delusional proportions. Ziprasidone has not been studied in patients with anorexia nervosa; hence, patients who are using this agent should be monitored for ECG changes and serum potassium abnormalities. Bulimia nervosa Antidepressants are effective as one component of an initial treatment program for most patients, with SSRIs having the most evidence for efficacy and the fewest difficulties with adverse effects. Of the SSRIs, fluoxetine is the best studied agent. Lithium is ineffective and should not be used.
	Binge eating disorder Antidepressants, particularly SSRIs, are associated with a short-term reduction in binge eating behavior, but not with substantial weight loss. Topiramate is effective in binge reduction and weight loss, although adverse effects may limit its use. Zonisamide is another option for patients with binge eating disorder.
Major Depressive Disorder (MDD)	
Institute for Clinical Systems Improvement: Major Depression in Adults in Primary Care (2013) ³⁰⁰	 Pharmacotherapy SSRIs, venlafaxine, duloxetine, desvenlafaxine, mirtazapine and bupropion are recommended as first-line antidepressant treatment options. Side effects may include headache, nervousness, insomnia, and sexual side effects.

Guideline	Recommendations
Julucinite	Secondary Amine Tricyclics (TCAs) are effective for the treatment of
	MDD; however, they are used less frequently as first-line agents due
	to their safety profile. Secondary amine tricyclics cause less
	orthostatic hypotension and sedation than do tertiary amine tricyclics.
	Monitoring blood levels and electrocardiogram (EKG) may be
	advised.
	Monoamine Oxidase Inhibitors (MAOIs) should only be used in
	patients who do not respond to other treatments because of their
	potential for serious side effects and the necessity of dietary
	restrictions.
	Augmentation therapy is used in patients whose depression is either treatment registrator partially responsive to treatment. Consultation
	treatment-resistant or partially responsive to treatment. Consultation with a behavioral health specialist is advised. The following agents
	may be added to antidepressant therapy: bupropion, buspirone,
	mirtazapine, triiodothyronine, stimulants, TCA-SSRI combination,
	lithium, and atypical antipsychotics.
American Psychiatric	Acute phase
Association:	· Pharmacotherapy:
Practice Guideline for	 An antidepressant medication is recommended as an initial
the Treatment of	treatment choice for patients with mild to moderate major
Patients With Major	depressive disorder (MDD) and definitely should be provided
Depressive Disorder (2010) ³⁰¹	for those with severe MDD.
(2010)	 Due to the fact that the effectiveness of antidepressant medications is generally comparable between classes and
	within classes of medications, the initial selection of an
	antidepressant medication will largely be based on the
	anticipated side effects; the safety or tolerability of these side
	effects; pharmacological properties of the medication and
	additional factors such as medication response in prior
	episodes, cost and patient preference.
	For the majority of patients, a selective serotonin reuptake This is a containing a selective serotonin reuptake
	inhibitor (SSRI), serotonin norepinephrine reuptake inhibitor (SNRI), bupropion or mirtazapine is optimal.
	in general, the use of nonselective monoamine oxidase inhibitors (MAOIs) should be restricted to patients who do not
	respond to other treatments.
	 In patients who prefer complementary and alternative
	therapies, S-adenosyl methionine or St John's Wort might be
	considered.
	Once an antidepressant has been initiated, the rate at which
	it is titrated to a full therapeutic dose should depend upon the
	patient's age, the treatment setting and the presence of co- occurring illnesses, concomitant pharmacotherapy or
	medication side effects.
	 During the acute phase of treatment, patients should be
	carefully and systematically monitored on a regular basis to
	assess their response to pharmacotherapy.
	 Determine the frequency of patient monitoring based upon
	the patient's symptom severity, co-occurring disorders,
	cooperation with treatment, availability of social supports and
	the frequency and severity of side effects with the chosen
	treatment.

Guideline	Recommendations
	 If side effects do occur, an initial strategy is to lower the dose
	of the antidepressants or to change to an antidepressant that
	is not associated with those side effects.
	Assessing the adequacy of treatment response:
	It is important to establish that treatment has been
	administered for a sufficient duration and at a sufficient
	frequency or, in the case of medication, dose. O Generally, four to eight weeks of treatment are needed
	before concluding that a patient is partially responsive or
	unresponsive to a specific intervention.
	Strategies to address non-response:
	 For individuals who have not responded fully to treatment,
	the acute phase of treatment should not be concluded
	prematurely, as an incomplete response to treatment is often
	associated with poor functional outcomes.
	If at least a moderate improvement in symptoms is not
	observed within four to eight weeks of treatment initiation, the diagnosis should be reappraised, side effects assessed,
	complicating co-occurring conditions and psychosocial
	factors reviewed and the treatment plan adjusted.
	It is important to assess the quality of the therapeutic alliance
	and treatment adherence.
	 If medications are prescribed, the psychiatrist should
	determine whether pharmacokinetic or pharmacodynamic
	factors suggest a need to adjust medication dose.
	 After an additional four to eight weeks of treatment, if the patient continues to show minimal or no improvement in
	symptoms, the psychiatrist should conduct another thorough
	review of possible contributory factors and make additional
	changes in the treatment plan.
	 There are a number of strategies available when a change in
	treatment seems necessary.
	§ For patients treated with an antidepressant,
	optimizing the medication dose is a reasonable first
	step if the side effect burden is tolerable and the upper limit of a medication dose has not been
	reached.
	In patients who have shown minimal improvement or
	experienced significant medication side effects, other
	options include augmenting the antidepressant with a
	depression-focused psychotherapy or with other
	agents or with changing to another non-MAOI
	antidepressant.
	S Patients may be changed to an antidepressant from the same pharmacological class or to one from a
	different class.
	Patients who have not responded to an SSRI, may
	respond to SNRI.
	Augmentation of antidepressant medications can
	utilize another non-MAOI antidepressant, generally
	from a different pharmacological class, or a non-
	antidepressant medication, such as lithium, thyroid hormone or a second generation antipsychotic.
	normone or a second generation antipsychotic.

Guideline	Recommendations
	 Continuation phase During the continuation phase of treatment, the patient should be carefully monitored for signs of possible relapse. Systematic assessment of symptoms, side effects, adherence and functional status is essential and may be facilitated through the use of clinician- and/or patient-administered rating scales. To reduce the risk of relapse, patients who have been treated successfully with antidepressant medications in the acute phase should continue treatment with these agents for four to nine months. In general, the dose used in the acute phase should be used in the continuation phase. To prevent a relapse of depression in the continuation phase, depression-focused psychotherapy is recommended, with the best evidence available for CBT.
	 Maintenance phase In order to reduce the risk of a recurrent depressive episode, patients who have had three or more prior MDD episodes or who have chronic MDD should proceed to the maintenance phase of treatment after completing the continuation phase. Maintenance therapy should also be considered for patients with additional risk factors for recurrence. Additional considerations that may play a role in the decision to use maintenance therapy include patient preference, the type of treatment received, the presence of side effects during continuation therapy, the probability of recurrence, the frequency and severity of prior depressive episodes, the persistence of depressive symptoms after recovery and the presence of co-occurring disorders. Such factors also contribute to decisions about the duration of the maintenance phase. For many patients, some form of maintenance treatment will be required indefinitely. An antidepressant medication that produced symptom remission during the acute phase and maintained remission during the continuation phase should be continued at a full therapeutic dose. For patients whose depressive episodes have not previously responded to acute or continuation treatment with medications or a depression-focused psychotherapy but who have shown a response to electroconvulsive therapy (ECT), maintenance ECT may be considered. Due to the risk of recurrence, patients should be monitored systematically and at regular intervals during the maintenance phase.
	 Discontinuation of treatment When pharmacotherapy is being discontinued, it is best to taper the medication over the course of at least several weeks. To minimize the likelihood of discontinuation symptoms, patients should be advised not to stop medications abruptly and to take medications with them when they travel or are away from home. A slow taper or temporary change to a longer half-life antidepressant may reduce the risk of discontinuation syndrome when discontinuing

Guideline	Recommendations
	effectiveness of counseling and psychodynamic psychotherapy in
	treating depression.
	Antidepressant drugs
	· Choice of antidepressant:
	 Discuss the choice of antidepressant with the patient,
	including any anticipated adverse events and potential drug
	interactions, and their perception of the efficacy and
	tolerability of any antidepressant they have previously taken.
	When an antidepressant is used, it should normally be an
	SSRI in a generic form. The SSRIs are equally effective as
	other antidepressants and have a favorable risk-benefit ratio.
	Fluoxetine, fluvoxamine and paroxetine are associated with a
	higher propensity for drug interactions than other SSRIs, and paroxetine is associated with a higher incidence of
	discontinuation symptoms than other SSRIs.
	Take into account toxicity in overdose when choosing an
	antidepressant for people at significant risk for suicide. Be
	aware that compared to other equally effective
	antidepressants routinely used in primary care, venlafaxine is
	associated with a greater risk of death from overdose, and tri-
	cyclic antidepressants (TCAs), except lofepramine, are
	associated with the greatest risk in overdose.
	 When prescribing drugs other than SSRIs, take the following
	into account: the increased likelihood of the person stopping
	treatment because of side effects with duloxetine, venlafaxine
	and TCAs, the specific cautions, contraindications and monitoring requirements for some drugs, that non-reversible
	MAOIs should normally be prescribed only by specialists and
	dosulepin should not be prescribed.
	Starting and initial phase of treatment:
	When prescribing antidepressants, explore any concerns the
	patient has. Explain the gradual development of the full
	antidepressant effect, the importance of taking the
	medication as prescribed, the need to continue treatment
	after remission, potential side effects, the potential for
	interactions with other medications, the risk and nature of
	discontinuation symptoms with all antidepressants and how
	these symptoms can be minimized and the fact that addiction
	does not occur with antidepressants.
	 If side effects develop early in antidepressant treatment, provide appropriate information and consider one of the
	following strategies: monitor symptoms closely where side
	effects are mild and acceptable to the patient, stop the
	antidepressant, change to a different antidepressant if the
	person prefers or consider short term concomitant treatment
	with a benzodiazepine if anxiety, agitation and/or insomnia
	are problematic (this should usually be for no longer than two
	weeks in order to prevent the development of dependence).
	 Patients who start on low dose TCAs and who have clear
	clinical response can be maintained on that dose with careful
	monitoring.
	o If the patient's depression shows no improvement after two to

Cuidalina	Decemmendations
Guideline	Recommendations
	four weeks with the first antidepressant, check that the drug has been taken regularly and in the prescribed dose. If response is absent or minimal after three to four weeks of treatment with a therapeutic dose of an antidepressant, increase the level of support and consider increasing the dose in line with the summary of product characteristics if there are no significant side effects or switching to another antidepressant. If the patient's depression shows some improvement by four weeks, continue treatment for another two to four weeks. Consider switching to another antidepressant if response is still not adequate, there are side effects or the person prefers to change treatment.
Obsessive Compulsive Dis	
American Psychiatric Association: Practice Guideline for the Treatment of Patients with Obsessive- Compulsive Disorder (2007) ³⁰³	 In choosing a treatment approach, the clinician should consider the patient's motivation and ability to comply with pharmacotherapy and psychotherapy. CBT and SSRIs are recommended as safe and effective first-line treatments for OCD. Combined treatment should be considered for patients with an unsatisfactory response to monotherapy, for those with co-occurring psychiatric conditions for which SSRIs are effective, and for those who wish to limit the duration of SSRI treatment. Clomipramine, fluoxetine, fluvoxamine, paroxetine, and sertraline are recommended first-line pharmacological agents. Because the SSRIs have a less troublesome side-effect profile than clomipramine, an SSRI is preferred for a first medication trial. CBT that relies primarily on behavioral techniques such as exposure and response prevention is recommended because it has the best evidentiary support. Most patients will not experience substantial improvement until 4 to 6 weeks after starting medication, and some who will ultimately respond will experience little improvement for as many as 10 to 12 weeks. Medication doses may be increased weekly or biweekly to the maximum dose comfortably tolerated and indicated. This maximum dose may exceed the manufacturer's recommended maximum dose in some cases. Higher doses may be appropriate for patients who have had little response to treatment and are tolerating a medication well. When initial therapy is inadequate, augmentation strategies may be preferred to switching strategies in patients who have a partial
	 response to the initial treatment. The psychiatrist should first consider augmentation of SSRIs with trials of different antipsychotic medications or with CBT. Patients who do not respond to one SSRI may be switched to a different SSRI. A switch to venlafaxine is less likely to produce an adequate response. For patients who have not benefitted from their first SSRI trial, a switch to mirtazapine can also be considered. SSRI nonresponders and partial responders may try augmentation with antipsychotic medications. Available evidence does not support the use of antipsychotic monotherapy. After first- and second-line treatments and well-supported

Guideline	Recommendations
Juludiiilo	augmentation strategies have been exhausted, less well-supported
	treatment strategies may be considered. These include augmenting
	SSRIs with clomipramine, buspirone, pindolol, riluzole, or once-
	weekly oral morphine sulfate.
Post-Traumatic Stress Dis	order (PTSD)
Veterans	<u>Pharmacotherapy</u>
Affairs/Department of	There is no evidence to support a recommendation for use of a

Clinical Practice	Benzodiazepines are not recommended for the prevention of ASD or
Guideline for the	PTSD.
Management of Post-	Monotherapy should be optimized before proceeding to subsequent
Traumatic Stress (2010) ³⁰⁴	strategies by monitoring outcomes, maximizing dosage (medication
(2010)	or psychotherapy), and allowing sufficient response time (for at least
	8 weeks). If there is some response and patient is tolerating the drug, therapy should be continued for at least another 4 weeks.
	1 1611 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1
	the initial drug to maximum tolerated, discontinuing the current agent
	and switching to another effective medication or augmenting with
	additional agents.
	Patients diagnosed with PTSD should be offered selective serotonin
	reuptake inhibitors (SSRIs), for which fluoxetine, paroxetine, or
	sertraline have the strongest support, or serotonin norepinephrine
	reuptake inhibitors (SNRIs), for which venlafaxine has the strongest
	support, for the treatment of PTSD.
	Mirtazapine, nefazodone, tricyclic antidepressants (TCAs)
	(amitriptyline and imipramine), or monoamine oxidase inhibitors
	(phenelzine) may also be used for the treatments for PTSD.
	Guanfacine and anticonvulsants (tiagabine, topiramate, or valproate)
	are not recommended to be used as monotherapy in the
	management of PTSD.
	The existing evidence does not support the use of bupropion, buspirone, trazodone, anticonvulsants (lamotrigine or gabapentin), or
	atypical antipsychotics as monotherapy in the management of PTSD.
	There is evidence against the use of benzodiazepines in the
	management of PTSD.
	There is insufficient evidence to support the use of prazosin as
	monotherapy in the management of PTSD.
	Atypical antipsychotics (risperidone or olanzapine or, quetiapine) are
	recommended as adjunctive therapy for the management of PTSD.
	Prazosin is recommended as adjunctive therapy for
	sleep/nightmares.
	There is insufficient evidence to recommend a sympatholytic or an
	anticonvulsant as an adjunctive therapy for the treatment of PTSD.
American Psychiatric	Pharmacotherapy
Association: Practice Guideline for	SSRIs are recommended as first-line pharmacotherapy option for
the Treatment of	PTSD. Other antidepressants, including trievelic antidepressants and
Patients with Acute	Other antidepressants, including tricyclic antidepressants and monoamine oxidase inhibitors (MAOIs), may also be beneficial in the
Stress Disorder and	treatment of PTSD.
Posttraumatic Stress	Benzodiazepines may be useful in reducing anxiety and improving
Disorder (2004)† ³⁰⁵	sleep. Although their efficacy in treating the core symptoms of PTSD
	has not been established, benzodiazepines are often used in trauma-
	nas not been established, benzediazepines are often assa in trauma-

Guideline	Recommendations
Juidemile	exposed individuals and patients with PTSD. However, due to the risk of dependence, increased incidence of PTSD after early treatment with these medications, or worsening of PTSD symptoms after withdrawal of these medications, benzodiazepines cannot be recommended as monotherapy in PTSD. Second generation antipsychotic medications (e.g., olanzapine, quetiapine, risperidone) may be helpful in individual patients with PTSD. Anticonvulsant medications (e.g., divalproex, carbamazepine, topiramate, lamotrigine), alpha-2-adrenergic agonists, and beta-adrenergic blockers may also be helpful in treating specific symptom clusters in individual patients.
	 Psychotherapy Cognitive behavior therapies may speed recovery and prevent PTSD when therapy is given over a few sessions beginning 2-3 weeks after trauma exposure. Early supportive interventions, psychoeducation, and case management appear to be helpful in acutely traumatized individuals, because these approaches promote engagement in ongoing care and may facilitate entry into evidence-based psychotherapeutic and psychopharmacological treatments. Encouraging acutely traumatized persons to first rely on their inherent strengths, their existing support networks, and their own judgment may also reduce the need for further intervention. Patients with ASD may be helped by cognitive behavior therapy and other exposure-based therapies. In addition, cognitive behavior therapy is an effective treatment for core symptoms of acute and chronic PTSD.
Schizophrenia	
National Institute for Health and Clinical Excellence: Psychosis and Schizophrenia in Adults: Treatment and Management (2014) ³⁰⁶	 If a person is considered to be at increased risk of developing psychosis: Offer individual cognitive behavioral therapy (CBT) with or without family intervention and Offer interventions recommended in National Institute for Health and Clinical Excellence guidance for people with any of the anxiety disorders, depression, emerging personality disorder or substance misuse. Do not offer antipsychotic medication: To people considered to be at increased risk of developing psychosis or With the aim of decreasing the risk of or preventing psychosis. First episode psychosis Oral antipsychotic medication in conjunction with psychological interventions
	 interventions Psychological interventions are more effective when delivered in conjunction with antipsychotic medication. The choice of antipsychotic medication should take into account: Metabolic (weight gain and diabetes)

Guideline	Recommendations
	extrapyramidal (akathisia, dyskinesia and dystonia)
	o cardiovascular (QT prolongation)
	 hormonal (increased prolactin)
	 o other (unpleasant subjective experience)
	 Do not initiate regular combined antipsychotic medication, except for
	short periods (for example, when changing medication)
	Acute episode
	· For people with an acute exacerbation or recurrence of psychosis or
	schizophrenia, offer oral antipsychotic medication in conjunction with
	psychological interventions
	 For people with an acute exacerbation or recurrence of psychosis or schizophrenia, offer oral antipsychotic medication or review existing
	medication. The choice of drug should be influenced by the same
	criteria recommended for starting treatment
	 A single antipsychotic agent is first line. Regular use of
	combination therapy should not be initiated except when
	changing agents.
	 If withdrawing antipsychotic medication, undertake gradually and monitor regularly for signs and symptoms of relapse.
	 Clinical response and side effects should be routinely monitored.
	 Large loading doses should not be used with antipsychotics.
	Combination antipsychotic therapy should not be prescribed except
	for a short duration while transitioning to a different antipsychotic
	agent.
	Due to the high risk of relapse following an acute episode, it is
	recommended to continue antipsychotic medications for up to one to two years.
	two years.
	Recovery/relapse prevention
	The goal of pharmacologic treatment is to prevent relapse and
	maintain the patient's quality of life.
	The same considerations for drug treatment should be given as in acute enjoyees petential side effects, nations observed and acute enjoyees.
	acute episodes: potential side effects, patient characteristics and preferences.
	 Depot preparations should be considered when adherence to oral
	medication is in question.
	Inadequate response to treatment
	 Factors for inadequate response should be evaluated including diagnosis, adherence to treatment, and comorbid conditions.
	 Consider clozapine for patients who have tried two antipsychotic
	agents (including one second generation antipsychotic) without
	significant improvement.
	Adding a second antipsychotic to clozapine may be considered for
	patients who are unresponsive to clozapine alone at standard doses;
	however, the use of more than 1 antipsychotic is not recommended in
	other situations except during the conversion from one agent to another.

	ideation, violence, or comorbid substance abuse.
	Stage 4
	A trial of clozapine and a first generation antipsychotic, second
	generation antipsychotic or electroconvulsive therapy are considered
	appropriate treatment options.
	Monotherapy should be exhausted before using combination therapy.
	Stage 5
	A trial of a single first or second generation antipsychotic not tried in
	Stages 1 or 2 is recommended.
	Stage 6
	Combination therapy (first and second generation antipsychotics,
	combination of second generation antipsychotics, first or second
	generation antipsychotics and electroconvulsive therapy, first or
	second generation antipsychotic and other agent-mood stabilizer) is
	recommended.
	Little evidence supports combination therapy due to increased risk of
	drug interactions, side effects and decreased safety and compliance.
American Psychiatric	Acute phase
Association:	Pharmacological treatment with aripiprazole, olanzapine, quetiapine,
Practice Guideline for	risperidone, or ziprasidone should begin at once with the first
the Treatment of Patients with	episode.
Schizophrenia (2004)† ³⁰⁸	Patients with persistent suicidal behavior or persistent hostility and aggressive behavior should be treated with clozapine.
Comzopinicina (2004)	Patients with tardive dyskinesia should be treated with clozapine or
	second generation antipsychotics.
	Patients sensitive to EPS side effects should be treated with a
	second generation antipsychotics (except clozapine); if risperidone is
	used, high doses are not recommended.
	Patients sensitive to prolactin elevations should be treated with a
	second generation antipsychotics (except clozapine and risperidone).
	Patients sensitive to weight gain, hyperglycemia, or hyperlipidemia
	should be treated with either aripiprazole or ziprasidone.
	Patient's nonadherent to pharmacological treatment should be
	treated with long-acting injectable antipsychotic agents.
	Agent should be chosen based on clinical circumstances and side

Guideline	Recommendations
Julianillo	effects.
	 For intolerable side effects, one of the following should be chosen: aripiprazole, a first generation antipsychotic, olanzapine, quetiapine, risperidone or ziprasidone. For an inadequate response, a different agent should be chosen: aripiprazole, clozapine, a first generation antipsychotic, olanzapine, quetiapine, risperidone or ziprasidone. For an inadequate response to a second agent, a different agent should be chosen; aripiprazole, clozapine, a first generation antipsychotic, olanzapine, quetiapine, risperidone or ziprasidone. Clozapine should be used to treat persistent psychotic symptoms. Consider electroconvulsive therapy for persistent severe psychosis, catatonia, and/or suicidal behavior in patients who failed prior treatments (including clozapine). Clozapine has the greatest efficacy on suicidal behavior and it should be considered in patients with suicidal ideation. Electroconvulsive therapy is used when a schizophrenic patient has not responded to antipsychotic treatment. When electroconvulsive therapy is administered in conjunction with an antipsychotic agent (either a first or second generation antipsychotic, it provides the largest benefit; however electroconvulsive therapy should not be used prior to a trial of clozapine.
Motabolio Sido Effonts	 Stabilization or maintenance phase The goal of medication in the stable phase is to minimize the risk of relapse, severity of side effects and possible residual symptoms. Continue with acute phase treatment. Electroconvulsive therapy should be considered for maintenance therapy for patients who have used electroconvulsive therapy in acute treatment with good response and who were not controlled with medication alone. Maintenance electroconvulsive therapy may help patients who have responded to acute electroconvulsive therapy and pharmacological prophylaxis is ineffective or intolerable. Evidence shows that antipsychotics should be used with electroconvulsive therapy maintenance. For intolerable side effects, another agent should be chosen; aripiprazole, a first generation antipsychotic, olanzapine, quetiapine, risperidone or ziprasidone.
Metabolic Side Effects	Occupation and the second seco
American Diabetes Association, American Psychiatric Association, American Association of Clinical Endocrinologists, North American Association for the Study of Obesity: Consensus Development Conference on Antipsychotic Drugs and Obesity and Diabetes (2004) ³⁰⁹	 Second-generation antipsychotics are more effective than first-generation antipsychotics in the treatment of negative symptoms and have fewer or no EPS side effects at clinically effective doses. The second generation antipsychotics are a widely used and they have important public health ramifications. Whether the prevalence of metabolic disorders is increased in psychiatric patient populations independent of drug therapy is difficult to determine. Study data suggests that the prevalence of both diabetes and obesity among individuals with schizophrenia and affective disorders is 1.5-2.0 times higher than in the general population. Whether a function of the illness itself or from the pharmacologic treatment, the limited amount of epidemiological data suggests an

Guideline	Recommendations
	increased prevalence of obesity, impaired glucose tolerance and type 2 diabetes in patients with psychiatric illness.
	 Treatment with a second generation antipsychotic particularly in patients with schizophrenia can cause a rapid increase in body weight that may not reach a plateau even after 1 year of treatment.
	 There have been numerous reports of the onset or exacerbation of diabetes following the initiation of therapy with many of the second generation antipsychotics and in some cases, hyperglycemia promptly resolved after the medication was discontinued.
	 According to current evidence, changes in serum lipids correspond with changes in body weight.
	 The benefits of first and second generation antipsychotics in certain patients could outweigh the potential risks.
	 Patients taking second generation antipsychotics should receive appropriate baseline screening and ongoing monitoring due to the health risks associated with these medications.
	 Further research is needed to better understand the relationship between first and second generation antipsychotics and significant weight gain, dyslipidemia and diabetes.

[†] This guideline can no longer be assumed to be current.

Table 15. Clinical Guidelines in Children and Adolescents

Guideline	Recommendations				
Anxiety Disorders					
American Academy of Child and Adolescent Psychiatry: Practice Parameter for the Assessment and Treatment of Children and Adolescents with Anxiety Disorders (2007) ^{1,310}	 The psychiatric assessment should consider differential diagnosis of other physical conditions and psychiatric disorders that may mimic anxiety symptoms. Treatment planning should consider a multimodal treatment approach. Psychotherapy should be considered as part of the treatment of children and adolescents with anxiety disorders. Cognitive behavioral therapy (CBT) has the most empirical support for the treatment of anxiety disorders in youths. SSRIs should be considered for the treatment of youths with anxiety disorders. There is no empirical evidence that any one SSRI is more effective than another for the treatment of childhood anxiety disorders. Medications other than SSRIs may be considered for the treatment of youths with anxiety disorders. These include venlafaxine, tricyclic antidepressants, buspirone, and benzodiazepines. 				
Bipolar Disorder					
American Academy of Child and Adolescent Psychiatry: Practice Parameter for the Assessment and Treatment of Children and Adolescents with Bipolar Disorder (2007) ^{†,311}	 Youth with suspected bipolar disorder must also be carefully evaluated for other associated problems, including suicidality, comorbid disorders (including substance abuse), psychosocial stressors, and medical problems. The diagnostic validity of bipolar disorder in young children has yet to be established. Caution must be taken before applying this diagnosis in preschool children. For mania in well-defined DSM-IV-TR bipolar I disorder, pharmacotherapy is the primary treatment. Standard therapy, based on adult literature, includes lithium, 				

Guideline	Recommendations				
	valproate, and/or atypical antipsychotic agents, with other adjunctive medications used as indicated.				
	The choice of medication should be based on 1) evidence of				
	efficacy, 2) illness phase, 3) presence of confounding				
	symptoms, 4) side effects, 5) patient's medication response				
	history, 6) patient and family preferences.				
	Clozapine is reserved for treatment-refractory cases because				
	of its side effect profile.				
	 Antidepressants may be used as adjunctive therapy for bipolar depression. 				
	Most youths with bipolar I disorder will require ongoing medication				
	therapy to prevent relapse; some individuals will need lifelong				
	treatment.				
	Psychopharmacological interventions require baseline and follow-up				
	symptoms, side effect (including patient's weight), and laboratory				
	monitoring as indicated.				
	A 6-8 week trial of a mood-stabilizing agent is recommended, Weight adapted decay before adding or substituting other.				
	using adequate doses, before adding or substituting other mood stabilizers.				
	For severely impaired adolescents with manic or depressive episodes				
	in bipolar I disorder, electroconvulsive therapy (ECT) may be used if				
	medications either are not helpful or cannot be tolerated.				
	Psychotherapeutic interventions are an important component of a				
	comprehensive treatment plan for early-onset bipolar disorder.				
	The treatment of bipolar disorder not otherwise specified (NOS)				
	generally involves the combination of psychopharmacology with behavioral/psychosocial interventions.				
American Academy of	Psychopharmacology				
Pediatrics:	Medication management is an important component of treatment of				
Collaborative Role of the	youth with bipolar disorder and is the primary treatment in cases of				
Pediatrician in the	well-defined mania.				
Diagnosis and	Mood stabilizers are the primary medications used to treat patients				
Management of Bipolar Disorder in Adolescents	with bipolar disorder (e.g., lithium, divalproex, lamotrigine,				
(2012) ³¹²	carbamazepine, oxcarbazepine, gabapentin, and topiramate; and atypical antipsychotics, including aripiprazole, olanzapine, quetiapine,				
(===)	risperidone, ziprasidone, paliperidone clozapine, asenapine, and				
	iloperidone.				
	Adjunctive medications include antidepressant medications and				
	"typical" antipsychotics, as well as medications for ADHD, anxiety,				
	and insomnia.				
	Medication selection should be based on efficacy, phase of illness, type of presentation (a.g., with payabotic symptoms), selectioned.				
	type of presentation (e.g., with psychotic symptoms), safety and adverse effect profile, history of medication response, and patient or				
	family preference.				
	Medication combinations are common, with some patients on five or				
	more drugs.				
	A diverse averate				
	Adverse events Mood stabilizer and atypical antipsychetic modications have a variety				
	 Mood stabilizer and atypical antipsychotic medications have a variety of adverse effects, interactions, and safety concerns. 				
	Weight gain and metabolic effects are common with the atypical				
	antipsychotics, although weight gain is also commonly associated				

Guideline	Recommendations
- Caracinito	with valproate and, to a lesser extent, lithium.
	 Children and adolescents may be more vulnerable than adults to weight gain from these medications and, thus, likely to be at higher risk of glucose and lipid abnormalities. Weight management potentially can be addressed with suggestions of diet and exercise as well as changing the dose and/or type of medication. Use of metformin may be of some help. Stable patients should be seen by their pediatrician every four to six months, with more frequent visits when there are active adverse effects, interactions, or safety issues.
National Institute for Health and Clinical Excellence: Bipolar Disorder: The Assessment and Management of Bipolar Disorder in Adults, Children and Adolescents, in Primary And Secondary Care (2014) ²⁹⁴	 Mania Consider the recommendations for adults (see above) Aripiprazole is recommended as an option for treating moderate to severe manic episodes in adolescents with bipolar I disorder, within its marketing authorization (that is, up to 12 weeks of treatment for moderate to severe manic episodes in bipolar I disorder in adolescents aged 13 and older). Aripiprazole was as effective as other antipsychotics for treating acute mania and had a comparable and acceptable adverse reaction profile.
	 Acute depressive episode in children and adolescents Patients with mild depressive symptoms, not requiring immediate treatment should be monitored. Children and adolescents with depressive symptoms needing treatment should be treated by specialists. A structured psychological therapy aimed at treating depression should be considered in addition to prophylactic medication. When prescribing an antidepressant, an antimanic agent should also be prescribed. Recombinations are limited to due to marketing authorization for antipsychotics and antidepressants in the UK.
Depressive Disorder	anapsycholics and antidepressants in the orc.
Depressive Disorder American Academy of Child and Adolescent Psychiatry: Practice Parameter for the Assessment and Treatment of Children and Adolescents With Depressive Disorders (2007) ^{†,313}	 The clinician should maintain a confidential relationship with the child or adolescent while developing collaborative relationships with parents, medical providers, other mental health professionals, and appropriate school personnel. The psychiatric assessment of children and adolescents should routinely include screening questions about depressive symptomatology. If the screening indicates significant depressive symptomatology, the clinician should perform a thorough evaluation to determine the presence of depressive and other comorbid psychiatric and medical disorders. The evaluation must include assessment for the presence of harm to self or others. The evaluation should assess for the presence of ongoing or past exposure to negative events, the environment in which depression is developing, support and family psychiatric history. The treatment of depressive disorders should always include an acute and continuation phase; some children may also require maintenance treatment.

Guideline	Recommendations				
Guideille	 Each phase of treatment should include psychoeducation, supportive management, and family and school involvement. Education, support, and case management appear to be sufficient treatment for the management of depressed children and adolescents with an uncomplicated or brief depression or with mild psychosocial impairment. For children and adolescents who do not respond to supportive psychotherapy or who have more complicated depressions, a trial with specific types of psychotherapy and/or antidepressants is indicated. Selective serotonin reuptake inhibitors (SSRIs) is the most commonly used pharmacotherapy for depression in youths. Clinical response should be assessed at 4-week intervals, and if the response is inadequate, the dose may be increased. To consolidate the response to the acute treatment and avoid relapses, treatment should always be continued for 6 to 12 months (MS). To avoid recurrences, some depressed children and adolescents should be maintained on treatment for longer periods of time. Depressed patients with psychosis, seasonal depression, and bipolar disorder may require specific somatic treatment. Atypical antipsychotics, combined with SSRIs, are recommended as the treatment of choice for depressed psychotic youths. Treatment should include the management of comorbid conditions. During all treatment phases, clinicians should arrange frequent follow-up contacts that allow sufficient time to monitor the subject's clinical status, environmental conditions, and if appropriate, 				
Obsessive Compulsive Dis	medication side effects.				
American Academy of					
Child and Adolescent Psychiatry:	 The psychiatric assessment of children and adolescents should routinely screen for the presence of obsessions and/or compulsions or repetitive behaviors. 				
Practice Parameter for the Assessment and Treatment of Children and	A complete psychiatric evaluation should be performed, including information from all available sources and comprising standard elements of history and a mental state examination, with attention to the presence of commonly occurring comorbid psychiatric disorders.				
Adolescents Obsessive-	A full medical, developmental, family, and school history should be				

Compulsive Disorders $(2012)^{314}$

- A full medical, developmental, family, and school history should be included with the psychiatric history and examination.
- When possible, CBT is the first-line treatment for mild to moderate cases of OCD in children.
- For moderate-severe OCD, medication is indicated in addition to CBT.
- SSRIs are the first-line medications recommended for OCD in children.
- Multimodal treatment is recommended if CBT fails to achieve a clinical response after several months or in more severe cases.
- For greatest efficacy, the combination of CBT and medication is the treatment of choice and should be considered the default option for first-line treatment in moderate to severe OCD.
- Medication augmentation strategies are reserved for treatmentresistant cases in which impairments are deemed moderate in at

Cuidalina	December detions				
Guideline	Recommendations				
	least one important domain of function despite adequate				
	monotherapy.				
	 Treatment resistance is defined as failure of adequate trials of at least two SSRIs or one SSRI and a clomipramine trial 				
	·				
	(as monotherapy) AND a failure of adequately delivered CBT (no improvement or substantial residual OCD symptoms after				
	8-10 total sessions). Children should have a minimum of 10				
	weeks of each SSRI or clomipramine at maximum				
	recommended or maximum tolerated doses, with no change				
	in dose for the preceding 3 weeks.				
	The most commonly used augmentation strategy is the addition of				
	atypical antipsychotics; though, there is no controlled data for the use				
	of these agents in children with OCD.				
	According to expert consensus, some children with treatment-				
	resistant OCD may benefit from judicious antipsychotic augmentation,				
	particularly children with tic disorders, poor insight, pervasive				
	developmental disorder symptoms, and mood instability. Clinical				
	experience indicates a minimum of two different adequate SSRI trials				
	or an SSRI and clomipramine before antipsychotic augmentation.				
	When atypical antipsychotics are used, at a minimum, there should				
	be regular weight, fasting lipid profile, serum glucose and adverse				
	event monitoring.				
	Other augmentation strategies include addition of clomipramine to an				
	SSRI or addition of either venlafaxine or duloxetine to an SSRI.				
Oppositional Defiant Diso	rder (ODD)				
American Academy of	Successful assessment and treatment of oppositional defiant disorder				
Child and Adolescent	(ODD) requires the establishment of therapeutic alliances with the				
Psychiatry	child and family.				
Practice Parameter for	Cultural issues need to be actively considered in diagnosis and				
the Assessment and	treatment.				
Treatment of Children	The assessment of ODD includes information obtained directly from				
and Adolescents with	the child as well as from the parents regarding the core symptoms of				
Oppositional Defiant	ODD, age at onset, duration of symptoms, and degree of functional				
Disorder (2007) ^{†,315}	impairment.				
	Clinicians should carefully consider significant comorbid psychiatric				
	conditions when diagnosing and treating ODD.				
	Clinicians may find it helpful to include information obtained				
	independently from multiple outside informants.				
	The use of specific questionnaires and rating scales may be useful in				
	evaluating children for ODD and in tracking progress.				
	The clinician should develop an individualized treatment plan based				
	on the specific clinical situation. Multimodal treatment is often				
	indicated.The clinician should consider parent intervention based on one of the				
	empirically tested interventions.				
	Medications may be helpful as adjuncts to treatment packages, for				
	symptomatic treatment and to treat comorbid conditions.				
	Medication should not be the sole intervention in ODD.				
	Nonresponsiveness to a specific compound should lead to a				
	trial of another class of medication rather than the rapid				
	addition of other medications.				
	 Treatment options include mood stabilizers, such as 				

Guideline	Recommendations				
Post-Traumatic Stress Dis	divalproex sodium, lithium, antipsychotics, and stimulants. Atypical antipsychotics are the most commonly prescribed medication class for the treatment of acute and chronic maladaptive aggression, regardless of diagnosis. Intensive and prolonged treatment may be required if ODD is unusually severe and persistent.				
American Academy of Child and Adolescent Psychiatry: Practice Parameter for the Assessment and Treatment of Children and Adolescents with Posttraumatic Stress Disorder (2010) ³¹⁶	 The psychiatric assessment should consider differential diagnoses of other psychiatric disorders and Physical conditions that may mimic posttraumatic stress disorder (PTSD). Treatment planning should consider a comprehensive treatment approach which includes consideration of the severity and degree of impairment of the child's PTSD symptoms. Treatment planning should incorporate appropriate interventions for comorbid psychiatric disorders. Trauma-focused psychotherapies should be considered first-line treatment for children and adolescents with PTSD. SSRIs can be considered for the treatment of children and adolescents with PTSD. There is insufficient data to support the use of SSRIs in the absence of psychotherapy for the treatment of childhood PTSD. Medications other than SSRIs may be considered for children and adolescents with PTSD. These include alpha- and beta-adrenergic blockers, atypical antipsychotics, non-SSRI antidepressants, mood-stabilizing agents, and opiates. 				
Schizophrenia					
American Academy of Child and Adolescent Psychiatry:	Adequate treatment requires the combination of psychopharmacological agents and psychosocial interventions.				
Practice Parameter for	<u>Pharmacotherapy</u>				
the Assessment and Treatment of Children and Adolescents with Schizophrenia (2001) ³¹⁷	 Antipsychotic agents are recommended for the treatment of the psychotic symptoms associated with schizophrenia. First-line agents include traditional neuroleptic medications (block dopamine receptors) and the atypical antipsychotic agents (that have a variety of effects, including antagonism of serotonergic receptors). Compared to traditional agents, the atypical antipsychotics are at least as effective for positive symptoms and they may be more helpful for negative symptoms. The use of antipsychotic drugs requires the following: adequate informed consent, documentation of target symptoms, baseline and follow-up laboratory monitoring, documentation of treatment response, monitoring for known side effects adequate therapeutic trials (appropriate dose for 4-6 weeks), In general, first-episode patients should receive some maintenance psychopharmacological treatment for 1 to 2 years after the initial episode, given the risk for relapse. Some patients may benefit from the use of adjunctive agents, including antiparkinsonian agents, mood stabilizers, antidepressants, or benzodiazepines. 				

Psychosocial Interventions Psychoeducational therapy for the patient, including ongoing education about the illness, treatment options, social skills training, relapse prevention, basic life skills training, problem-solving skills and strategies, is recommended. Psychoeducational therapy for the family, to increase their understanding of the illness, treatment options, prognosis and for developing strategies to cope with the patient's symptoms, is recommended. National Collaborating Centre for Mental Health, National Institute for Health and Clinical Excellence: Psychosis and Schizophrenia in Children and Young People, Recognition and Management (2013) ³¹⁸ If the child or young person and their parents or carers wish to try psychological interventions (family intervention with individual CBT. Agree a time limit (one month or less) for reviewing treatment options, including introducing antipsychotic medication. The choice of antipsychotic medication should be made by the parents or carers of younger children, or jointly with the young person and their parents or carers of younger children, or jointly with the young person and their parents or carers of younger children, or jointly with the young person and their parents or carers of younger children, or jointly with the young person and their parents or carers of younger children, or jointly with the young person and their parents or carers of younger children, or jointly with the young person and their parents or carers of younger children, or jointly with the young person and their parents or carers of younger children, or jointly with the young person and their parents or carers of younger children, or jointly with the young person and their parents or carers of younger children, or jointly with the young person and their parents or carers of younger children, or jointly with the young person and their parents or cares of younger children, or jointly with the young person in people aged 15 to 17 years who are intolerant of risperidone, or for whom risperido	Guideline	Recommendations

	and patient diag	nosis.			-		
	however, certain specific atypical	antipsychoti	ic.				
	 The use of multiple psychotropic medications in refractory patients may, at times, be necessary but has not been studied rigorously and clinicians should proceed with caution. 						
	The simultaneous use of multiple atypical antipsychotics has not been studied rigorously and generally should be avoided.						
	 Consideration of medication combinations should only begin after patients are refractory to medication trials of each atypical antipsychotic and, perhaps, older antipsychotic 						
	agents or other evidence-supported agents (such as mood stabilizers) at the appropriate target dose(s) and length of treatment.						
	After the failure of one atypical antipsychotic (after 4-6 week therapy), the selection of an alternative agent may include consideration of						
	 another atypical antipsychotic and/or a medication from a different class of drugs. The acute and long-term safety in children and adolescents has not 						
	been fully evaluated and therefore careful and frequent monitoring of side effects is indicated. See table below.

Conclusions

The antipsychotics are divided into two distinct classes: typical antipsychotics, also called first-generation antipsychotics (FGAs), and the atypical antipsychotics, which collectively are also referred to as second-generation antipsychotics (SGAs). These agents are available in various dosage forms including capsules, tablets, injections, oral solutions, sublingual tablets, and orally disintegrating tablets.

The FGAs are effective in the treatment of positive symptoms of schizophrenia (agitation, aggression, delusions and hallucinations), but are thought to be less effective against the negative symptoms (avolition, anhedonia, alogia, affective flattening and social withdrawal). FGAs are also approved for the management of various manifestations of other psychotic disorders and the suppression of motor and phonic tics in patients with Tourette's disorder. Adverse events are common with the FGAs, potentially resulting in these agents being used in a more limited capacity.

Each of the SGAs has a distinctive neuropharmacologic and adverse event profile, mechanism of action and chemical structure. It should be noted that paliperidone is an active metabolite of risperidone and therefore carries some similarity in chemical structure and pharmacologic effects with the parent drug. When compared to the FGAs, the SGAs are associated with a lower risk of extrapyramidal symptoms (EPS) and tardive dyskinesia, making them a generally better-tolerated treatment option. The SGAs are approved for the treatment of bipolar disorder and/or schizophrenia and are often a preferred treatment over the FGAs since they are thought to have a more favorable outcome in the treatment of the negative symptoms of schizophrenia. Moreover, several agents have recently been approved for the treatment of schizoaffective disorder, irritability associated with autistic disorder and for the adjunctive treatment of major depressive disorder. While the use of atypical antipsychotics in pediatric patients is in many instances off-label, aripiprazole, asenapine, olanzapine, paliperidone, quetiapine, and risperidone have been Food and Drug Administration (FDA)-approved for children and/or adolescents with bipolar disorder and/or schizophrenia. Aripiprazole and risperidone are also FDA-approved for use in children and adolescents suffering from irritability secondary to autistic disorder.

Meta-analyses evaluating the roles of available atypical antipsychotics in the treatment of schizophrenia suggest that all agents are significantly more effective than placebo. He trends for respective efficacy suggest that clozapine is the most effective agent in the class, followed by olanzapine and risperidone. In clinical trials, aripiprazole tended to exhibit lower efficacy than the other agents. He treatment option (taking into account both efficacy and tolerability). The next best treatment options, in order of decreased efficacy were olanzapine, haloperidol, quetiapine, carbamazepine, aripiprazole, valproate, lithium, and ziprasidone. Lamotrigine, topiramate and gabapentin were found to be less effective than placebo. In the management of major depressive disorder, aripiprazole, quetiapine, and risperidone augmentation therapies were associated with improved outcomes.

Augmentation with atypical antipsychotics for the treatment of patients with anxiety disorders was associated with mixed results. ^{79,80} Atypical antipsychotics were associated with a moderate effect on anger associated with borderline personality disorder, with no effect on depressive symptoms. ^{81,82} Mood stabilizers were found to offer greater benefit in these patients. ⁸² All evaluated atypical antipsychotics were found to improve symptoms of agitation/aggression secondary to dementia. ⁸³⁻⁹¹ When used as a part of multimodal therapy, SGAs have some limited evidence for use in patients with anorexia. ⁹⁷⁻⁹⁹ However, the Agency for Healthcare Research and Quality's review does not recommend the use of these agents for eating disorders. ¹⁸⁹ Available evidence in pediatric patients with clinically significant aggression suggests a potential benefit in the short-term use of SGAs (majority of evidence is with risperidone). ¹¹²⁻¹³⁰ Aripiprazole and risperidone are supported by evidence-based medicine for use in patients with irritability/agitation or aggression secondary to an autistic spectrum disorder. ¹³⁴⁻¹⁵⁴ Atypical

antipsychotics (aripiprazole, quetiapine, risperidone, olanzapine and ziprasidone) were also shown to reduce tic severity in patients with Tourette's syndrome. 175-183,189

Available evidence suggests that, except for clozapine, olanzapine is associated with greater weight gain compared to all other atypical antipsychotic agents. In contrast, ziprasidone is associated with a low incidence of weight gain.²¹⁴ A systematic review by Safer et al suggests that weight gain is greater in children and adolescents than in adults.²⁵⁷ In addition, olanzapine is associated with a greater risk of other metabolic side-effects, such as hyperglycemia and hypercholesterolemia, vs other atypical antipsychotics. Likewise, data from the FDA Adverse Reporting System (AERS) indicates that the risk of experiencing a diabetes-related adverse event is greatest with olanzapine, followed by risperidone, and least with ziprasidone and aripiprazole, across all age groups.²⁴³ Of note, despite the increased metabolic risk with olanzapine, the Zodiac study failed to find a significant difference in non-suicide mortality between patients exposed to olanzapine and ziprasidone.¹⁹⁰ Risperidone is associated with the greatest risk of prolactin elevation-related adverse events.^{46-58,68-72,260} In addition, risperidone, aripiprazole and ziprasidone are associated with a high incidence of EPS adverse events.²²² Quetiapine is associated with the least risk of EPS adverse events.²²² The incidence of sexual dysfunction was noted to be higher with the use of olanzapine, risperidone, and clozapine than with quetiapine, ziprasidone or aripiprazole.²³⁶

As mentioned previously, available clinical consensus guidelines do not differentiate among the different SGAs; however, they provide guidance on the place in therapy of antipsychotics as a class in various disease states, both FDA-approved and off-label. The use of these agents for the treatment of schizophrenia is recognized by national and international guidelines as a mainstay in therapy. 306-308 Lithium, valproate and/or antipsychotics are recommended as initial therapy of bipolar disorder. 293-296 Furthermore, the American Psychiatric Association guideline recommends the use of antipsychotics for the management of psychosis or agitation in patients with dementia.²⁹⁷ For the treatment of anxiety disorders, sertraline is recommended as a first-line pharmacotherapeutic agent.^{291,292} Second-line treatment options include serotonin norepinephrine reuptake inhibitors (SNRIs) or switching to alternative selective serotonin reuptake inhibitors (SSRIs). Augmentation therapy with antipsychotics is an option in treatment-refractory patients but the guidelines recommend that initiation of combination therapy be limited to specialists. In major depressive disorder, first-line treatment options include SSRIs, SNRIs, bupropion or mirtazapine. 300-302 Antipsychotic augmentation therapy is an option for patients who have failed antidepressant monotherapy. In obsessive-compulsive disorder, SSRIs and cognitive behavioral therapy are recommended as first-line treatment options.³⁰³ Patients who have failed an SSRI trial may be offered augmentation therapy with an antipsychotic or cognitive behavioral therapy. Similarly, SSRIs and SNRIs are considered to be first-line treatment options for the treatment of post-traumatic stress disorder (PTSD), 304,305 Atypical antipsychotics may be used as adjunctive therapy for the management of treatment-refractory PTSD. Furthermore, the European Society for the Study of Tourette Syndrome guideline recommends risperidone as a first-line agent for the treatment of tics. ³¹⁹ Aripiprazole has a role in treatment-refractory patients. Moreover, the American Academy of Child and Adolescent Psychiatry (AACAP) guideline acknowledges that atypical antipsychotics are the most commonly prescribed class of drugs for the treatment of maladaptive aggression, regardless of diagnosis; yet emphasize that pharmacotherapy should not be used as the only intervention in children with oppositional defiant disorder. 314 Although the antipsychotics are not addressed in national and international insomnia treatment guidelines, the National Institute of Health (NIH) Consensus and State-of-the-Science Statement on Manifestations and Management of Chronic Insomnia in Adults state that due to the lack of evidence supporting the short and long term efficacy of antipsychotics, in addition to their significant risks, their use in the treatment of chronic insomnia cannot be recommended. 321

In a practice guideline on the use of atypical antipsychotics in children and adolescents, issued by the AACAP in 2011, the panel recommends that prior to initiation of antipsychotic therapy patients should undergo a thorough diagnostic assessment, evaluation for comorbid medical conditions and concomitant medications. Furthermore, a multidisciplinary plan that includes education and psychotherapy should be established. The prescriber should also have a thorough discussion of the risks and benefits of psychotropic medication. Of the atypical antipsychotics, risperidone is recognized as an agent with the

most substantial amount of methodologically stringent evidence for use in pediatric patients. Of note, combination antipsychotic therapy has not been well studied and should be avoided, unless the patient has failed trials of all antipsychotic agents, used as monotherapy. In addition, there is almost no data to support the use of atypical antipsychotics in pre-school aged children. The guideline recommends a marked amount of caution before using these agents in pre-schoolers. Given the risk of metabolic side-effects, pediatric patients receiving atypical antipsychotic therapy should be closely monitored for changes in weight, blood pressure, fasting plasma glucose and lipid profile.

Therapeutic duplication with the atypical antipsychotics is also of concern in adults due to the inherent risks of polypharmacy (eg, adverse events, drug interactions, decreased adherence) and lack of sufficient evidence and guidelines supporting clinical value with such practice. This risk is exemplified by results of clinical trials demonstrating that combination antipsychotic therapy results in a greater risk of metabolic adverse events. ²³²⁻²⁴⁰

Appendix Ia: Summary of the Strength of Evidence for Off-Label Efficacy Outcomes (adopted from

2011 AHRQ systematic review)¹⁸⁹

Indication	Strength of Evidence	Findings	Conclusions
Dementia	High	The 2011 meta-analysis of PCTs, aripiprazole, olanzapine, and risperidone were superior to placebo as treatment of behavioral symptoms as measured by total scores on BEHAVE-AD, BPRS, and NPI. Effect sizes were generally considered to be "small" in magnitude. Psychosis –risperidone was superior to placebo, as measured by thepsychosis subscales of the BEHAVE-AD, BPRS, and NPI. Results for aripiprazole did not meet conventional levels of statistical significance. Agitation – Aripiprazole, olanzapine and risperidone were superior to placebo, as measured by the agitation subscales of the BEHAVE-AD, BPRS, NPI, and CMAI. Three head to head trials compared atypicals; none was found superior.	Aripiprazole, olanzapine, and risperidone have efficacy as treatment for behavioral symptoms of dementia.
Depression			
Augmentation of SSRI/SNRI	Moderate (risperidone, aripiprazole, quetiapine)	The meta-analysis used "response" to treatment and remission as outcome. Pooling trials that reported the HAM-D as outcome, the relative risk of responding for participants taking	Aripiprazole, quetiapine, and risperidone have efficacy as augmentation to SSRIs/SNRIs for major depressive disorder.
	(olanzapine,	quetiapine or risperidone was	Olanzapine and

Indication	Strength of Evidence	Findings	Conclusions
	ziprasidone)	significantly higher than for placebo. Other trials reported MADRS scores; the relative risk of responding for participants taking aripiprazole was significantly higher than those taking placebo. Risperidone was included in two trials. These reported the drug superior to placebo. The relative risk of responding for participants taking aripiprazole was significantly higher than those taking placebo. Olanzapine had only two trials, so pooling was not performed; the trials reported olanzapine superior to placebo. In one available ziprasidone trial, the drug was superior to placebo in terms of MADRS scores. One trial compared ziprasidone at differing levels augmenting sertraline to sertraline alone. This trial found a greater improvement in CGI-S and MADRS scores augmenting with ziprasidone at 160mg than either augmentation with ziprasidone at 80mg or sertraline alone. However, there was no significant difference in	ziprasidone may also have efficacy.
Monotherapy	Moderate	HAMD-17, CGI-I or HAM-A scores. Olanzapine alone was no better than placebo in improving symptoms at six or 12 weeks in three trials. Outcomes were too	Olanzapine does not have efficacy as monotherapy for major depressive disorder.
		In five PCTs, quetiapine was superior according to relative risk of both responding and remitted as measured by MADRS.	Quetiapine has efficacy as monotherapy for major depressive disorder
Obsessive Compu			
Augmentation of SSRIs	Moderate (risperidone)	The 2006 meta-analysis pooled results of nine trials of risperidone, olanzapine, or quetiapine as	Risperidone has efficacy in improving OCD symptoms when used as
	Low (olanzapine)	augmentation therapy in patients who were resistant to treatment with SSRI. Atypical antipsychotics had a clinically important benefit,	an adjunct to SSRI in treatment refractory patients.

Indication	Strength of Evidence	Findings	Conclusions
	Evidence	(measured by the Yale-Brown Obsessive-Compulsive Scale (YBOCS), when used as augmentation therapy. Relative risk of "responding" significant for augmentation with quetiapine and risperidone.	Olanzapine may have efficacy. Quetiapine is more efficacious than ziprasidone and clomipramine. e.
		quetiapine produced a significant reduction in Y-BOCS score, while	
Augmentation of citalopram	Low (quetiapine) Very low (risperidone)	Clomipramine did not. One trial of risperidone reported no differences between groups in achieving a response to therapy, but patients maintained on risperidone had a significantly longer period of time to relapse compared to placebo (102 vs 85 days).	Quetiapine and risperidone may be efficacious as augmentation to citalopram in OCD patients.
		Two trials found quetiapine superior to placebo as augmentation for citalopram, according to Y-BOCS and CGI-I scores.	
Post-Traumatic Stress Disorder	Moderate (risperidone) Low (Olanzapine) Very Low (Quetiapine)	Three trials enrolled men with combat-related PTSD; these showed a benefit in sleep quality, depression, anxiety, and overall symptoms when risperidone or olanzapine was used to augment therapy with antidepressants or other psychotropic medication.	Risperidone is efficacious in reducing combat-related PTSD symptoms when used as an adjunct to primary medication.

Indication	Strength of Evidence	Findings	Conclusions
		Three trials of olanzapine or risperidone as monotherapy for abused women with PTSD were inconclusive regarding efficacy.	
		One trial found a three-fold decline in PTSD Scale (CAPS) scores in patients treated with quetiapine monotherapy compared to placebo.	
		There were too few olanzapine studies (two) to pool; one reported olanzapine superior to placebo, while one did not.	
		A meta-analysis of risperidone, using CAPS scores as outcome, found risperidone to be superior to placebo.	
		In a meta-analysis by condition, atypical antipsychotics were efficacious for combat-related PTSD but not PTSD in abused women.	
Personality Disord			
Borderline	Low (aripiprazole) Very low (quetiapine, olanzapine)	Four trials provide evidence that olanzapine is superior to placebo and may be superior to fluoxetine. The benefit of adding olanzapine to dialectical therapy in one trial was small. Two trials of olanzapine found no difference from placebo in any outcomes compared to placebo.	Olanzapine had mixed results in seven trials, aripiprazole was found efficacious in two trials, quetiapine was found efficacious in one trial, and ziprasidone was found not efficacious in one trial.
		Aripiprazole was superior to placebo in one small trial. Another trial found aripiprazole superior to placebo in improving SCL-90, HAM-D, and HAM-A scores at 8 months and less self-injury at 18 months.	
		A trial of ziprasidone found no significant difference in CGI-BPD, depressive, anxiety, psychotic or impulsive symptoms compared to placebo at 12 weeks.

Appendix Ib: Summary of Adverse Events of Atypical Antipsychotics for Off-Label Use (adopted from 2011 AHRQ systematic review)¹⁸⁹

Adverse Event	Head-to-Head Studies	Active Comparator Studies	Placebo-Controlled Studies
Weight Gain			
Elderly	In one large trial (CATIE-AD) patients who were treated with olanzapine,	More common in patients taking olanzapine than risperidone or	According to the meta- analysis, more common in patients taking olanzapine and risperidone than

Adverse Event	Head-to-Head Studies	Active Comparator Studies	Placebo-Controlled Studies
	quetiapine, or risperidone averaged a monthly gain of 1.0, 0.7, and 0.4 lbs respectively, compared to a monthly weight loss of 0.9 lbs for placebo patients.	conventional antipsychotics, particularly if their BMI was less than 25 at baseline, according to a large cohort study.	placebo.
Adults	More common in olanzapine patients than ziprasidone patients in one trial.	More common among patients taking olanzapine than patients taking conventional antipsychotics in three trials. More common in patients taking aripiprazole than patients taking conventional antipsychotics in one trial. More common among patients taking olanzapine than patients taking mood stabilizers in two trials.	According to the meta- analysis, more common in patients taking aripiprazole, olanzapine, quetiapine, and risperidone than placebo.
Children/Adolescents	No head to head studies	No difference between clonidine and risperidone in one trial.	More common in patients taking risperidone in two PCTs. No difference in one small PCT of ziprasidone.
Mortality-in the elderly	No difference between olanzapine and risperidone according to a meta-analysis of six trials of olanzapine published in 2006.	Six large cohort studies compared mortality in elderly patients taking atypical and conventional antipsychotics. Four of these studies found a significantly higher rate of death with conventional antipsychotics, while two found no statistical difference in mortality between the drug classes.	The difference in risk for death was small but statistically significant for atypicals, according to a 2006 meta-analysis which remains the best available estimate. Sensitivity analyses found no difference between drugs in the class. Patients taking atypicals had higher odds of mortality than those taking no antipsychotics in the two cohort studies that made that comparison. There are no trials or large observational studies of ziprasidone in this population.
Endocrine	1	<u>I</u>	- - - - - - - - - - - - -

Adverse Event	Head-to-Head Studies	Active Comparator Studies	Placebo-Controlled Studies
Elderly	No evidence reported	No evidence reported	No difference in endocrine events in risperidone patients in one PCT. Regarding diabetes, risk was elevated but not statistically significant in one industry-sponsored cohort study of olanzapine patients.
Adults	Diabetes more common in patients taking olanzapine than patients taking risperidone in one trial.	No evidence reported	Endocrine events more common in patients taking quetiapine, risperidone, and ziprasidone in one PCT each. More common in olanzapine in two pooled PCTs. Diabetes more common in patients taking quetiapine in six pooled PCTs; however, the pooled odds ratio was elevated at 1.47 but not statistically significant. More common in olanzapine patients in one PCT; the odds ratio of 5.14 was not statistically significant, with very wide confidence intervals (0.6 to 244). Lower odds of diabetes in risperidone patients in one large observational study.
Cerebrovascular Accident (CVA)	No evidence reported	Hospitalization for CVA was increased in the first week after initiation of typical antipsychotics, but not for initiation of atypicals in a large cohort study.	More common in risperidone patients than placebo according to four PCTs pooled by the manufacturer. In a meta-analysis of PCTs, risperidone was the only drug associated with an increase. More common in olanzapine than placebo according to five PCTs pooled by the manufacturer.
Extrapyramidal Sympto Elderly	ms (EPS) More common in	No evidence reported	More common in nationts
Liderry	patients taking aripiprazole and risperidone patients than patients taking	No evidence reported	More common in patients taking risperidone, according to the meta-analysis. Quetiapine and aripiprazole were not

Less likely in patients taking olanzapine or aripiprazole than patients taking conventional antipsychotics in one trial each.	olanzapine in one PCT. More common in patients taking aripiprazole, quetiapine, and ziprasidone than placebo according to the metaanalysis.
Sedation	T	T	T
Elderly	More common in elderly patients taking olanzapine or quetiapine than risperidone according to the meta-analysis, but not statistically significant.	No difference in one trial of olanzapine vs benzodiazepines. No difference in three trials of olanzapine and three of risperidone vs conventional antipsychotics.	More common in patients taking aripiprazole, olanzapine, quetiapine, and risperidone than placebo according to the meta-analysis.
Adults	More common in patients taking quetiapine than risperidone in two trials. No difference in one trial of risperidone vs olanzapine.	Olanzapine patients had higher odds than mood stabilizer patients in two trials. More common in olanzapine and quetiapine patients than SSRIs patients in three and two trials respectively. Olanzapine patients had lower odds than patients taking conventional antipsychotics in the pooled analysis of three trials.	More common in patients taking aripiprazole, olanzapine, quetiapine, risperidone, and ziprasidone than placebo in the meta-analysis.
Children/Adolescents	No head-to-head trials	No difference in one small trial of clonidine vs risperidone. More patients on haloperidol than risperidone reported sleep problems in one trial.	Less common in aripiprazole patients than placebo patients in one PCT. No difference from placebo in one small PCT of ziprasidone.

Appendix IIb: Summary of Evidence for Adverse Events in Children and Adolescents (adopted from 2012 AHRQ systematic review)⁹⁶

Outcome	Strength of Evidence	SGA vs SGA	Placebo-Controlled Studies
Dyslipidemia	Low	Aripiprazole was significantly favored over olanzapine (RR, 0.25; 95% CI, 0.08 to 0.8) ^a and 95% CI, 271.3 to 27.4). ^a No significant differences were observed for clozapine vs olanzapine, olanzapine vs quetiapine and quetiapine vs risperidone.	Significant effect in favor of placebo over aripiprazole (RR, 2.5; 95% CI, 1.4, 4.4) ^a , olanzapine (RR, 2.4; 95% CI, 1.2 to 4.9; I ² , 45%), and quetiapine (RR, 2.4; 95% CI, 1.1 to 5.4; I2, 0%).
	Moderate	Significant effect in favor of risperidone compared with olanzapine for cholesterol (MD, 10.2 mg/dL; 95% CI, 3.1 to 17.2; I ² , 0%) and triglycerides (MD, 17.3 mg/dL; 95% CI, 3.5 to 31.1; I2, 0%).	NA
EPS	Low	No significant difference for clozapine vs olanzapine, clozapine vs risperidone, olanzapine vs quetiapine, olanzapine vs risperidone, quetiapine vs risperidone.	No significant differences for placebo compared to olanzapine or quetiapine.
	Moderate	NA	Significant effect in favor of placebo over aripiprazole (RR, 4.2; 95% CI, 2.4 to 7.2; I ² , 0%) and risperidone (RR, 2.7; 95% CI, 1.4 to 4.9; I ² , 0%).
Insulin Resistance	Low	No significant difference for olanzapine vs quetiapine, olanzapine vs risperidone or quetiapine vs risperidone.	No significant difference between aripiprazole and placebo or olanzapine and placebo.
Prolactin-related sexual side effects	Low	Significant effect in favor of clozapine over olanzapine (MD, 210.8 ng/dL; 95% CI, 216.7 to 24.8; I ² , 21%). No significant difference for quetiapine vs	Significant effect in favor of placebo over risperidone in seven or eight studies (not pooled due to heterogeneity). No

Outcome	Strength of Evidence	SGA vs SGA	Placebo-Controlled Studies
		risperidone.	significant difference for quetiapine compared to placebo.
	Moderate	Significant effect in favor of olanzapine over risperidone (RR, 0.4; 95% CI, 0.2 to 0.6; I ² , 0%).	Significant effect in favor of aripiprazole over placebo (MD, 24.1 ng/mL; 95% CI, 26.3 to 21.8; I2, 0%). Significant effect in favor of placebo over olanzapine (MD, 11.5 ng/mL; 95% CI, 8.8 to 14.1; I2, 0%).
Sedation	Low	No significant differences for clozapine vs olanzapine, olanzapine vs quetiapine, olanzapine vs risperidone, quetiapine vs risperidone.	Significant effect in favor of placebo over aripiprazole (RR, 2.7; 95% CI, 1.1 to 6.5; I2, 76%). No significant difference in placebo comparisons with olanzapine and quetiapine.
	Moderate	NA	Significant effect in favor of placebo over risperidone (RR, 2.9; 95% Cl, 1.5 to 5.5; I ² , 32%) and ziprasidone (RR, 3.0; 95% Cl, 1.7 to 5.2; I ² , 0%).
Weight gain	Low	Significant effect in favor of aripiprazole over olanzapine (MD, 24.1 kg; 95% CI, 25.5 to 22.7),a quetiapine (MD, 21.6 kg; 95% CI, 23.0 to 20.3) ^a and risperidone (MD, 22.3 kg; 95% CI, 23.9 to 20.7).a No significant difference for clozapine vs olanzapine, clozapine vs risperidone, and quetiapine vs risperidone.	No significant difference for ziprasidone compared to placebo.
	Moderate	Significant effect in favor of quetiapine over olanzapine (RR, 1.5; 95% CI, 1.1 to 2.0; I ² , 0%) and risperidone over olanzapine (MD, 2.4 kg; 95% CI, 1.5 to 3.3; I ² , 72%).	Significant effect in favor of placebo over aripiprazole (MD, 0.8 kg; 95% CI, 0.4 to 1.2; I^2 , 13%), olanzapine (MD, 4.6 kg; 95% CI, 3.1 to 6.1; I2, 70%), quetiapine (MD, 1.8 kg; 95% CI, 1.1 to 2.5; I^2 , 49%), and risperidone (MD, 1.8 kg; 95% CI, 1.5 to 2.1; I^2 , 0%).

AE=adverse event; EPS=EPS symptom; RR=relative risk.
a=Only 1 study contributed to this estimate; therefore, an I² value could not be calculated.
